"As regards the age at which paraplegia begins, we have notes of 156 cases, showing that it may appear at any age, but that certain forms belong more to certain ages than to others. For instance, reflex paraplegia is the most common form in children, myelitis is the most frequent cause of paraplegia in adults, and non-inflammatory softening the predominant cause of this paralysis in old age.

"*Signification of the various Symptoms belonging to, or co-existing with, Paraplegia.*—We have given many details as regards these symptoms in our descriptions of the reflex paraplegia (Lect. I. and II.); of myelitis, meningitis, and congestion of the cord and its meninges (Lect. III.); of the non-inflammatory softening, hæmorrhage, and tumours (Lect. IV.) We will now take up each of the most important symptoms, and show to what form of paraplegia it is especially attached, and what is its cause.

"1st. *Cramps, Twitchings, and other Convulsions.*—The signification of tonic or chlonic convulsions in paralysed muscles, in cases of paraplegia, is quite evident: they are incontestable results of an irritation of either the anterior roots of the spinal nerves, the spinal cord, or the sensitive nerves in any part of their length, through a reflex action. In cases of myelitis it is chiefly under the form of cramps that convulsions occur; the frequency of these spasms is one of the characteristics of this affection. In cases of tumours pressing upon the spinal cord, especially upon its posterior surface, cramps are not so frequent as twitchings or a general spasm producing a drawing up of the lower limbs, which sometimes remain permanently in a state of spasmodic flexion. In cases of chronic meningitis, or congestion of the spinal cord or its membranes, twitchings are more frequent than cramps. In cases of reflex paraplegia, the external irritation that produces the paralysis sometimes produces also spasmodic movements by a reflex action. Especially in those cases where the rectum or the urethra are the parts from which starts the irritation, there is what the patient calls a *catchiness* or a drawing up of the legs. In cases of hæmorrhage in the spinal canal, tetanic convulsions are frequently observed. Rigid spasms of the muscles of the back are amongst the most prominent symptoms of spinal meningitis. Amongst the affections of the spinal cord that produce paraplegia, one of the most frequent—the non-inflammatory or white softening—is characterised by a total absence of cramps, twitchings, or other convulsions.

"On the whole, some form of morbid muscular contractions exists constantly in myelitis or spinal meningitis, and frequently in cases of congestion of the spinal cord or its membranes, or of tumours or other cause of pressure upon the spinal cord, and also, sometimes (by a reflex action), in cases of reflex paraplegia. On the other hand, a complete absence of morbid contractions will be observed in all cases of non-inflammatory softening, and in the majority of cases of reflex paraplegia.

"2nd. *Referred Sensations in the Paralysed Limbs.*—These morbid sensations, like morbid contractions, are the results of some kind of irritation, and, as we have tried to prove in Lect. III., the vital properties of the spinal cord changing when it is inflamed, these sensations may be produced by an inflammation of the grey matter. The various kinds of conductors passing through or along the grey matter being then irritated, give origin to all kinds of sensations which are referred to the various parts of the lower limbs. Sensations of cold or of heat, of touch (formication, tickling, pressure, tightness, &c.), of pain (pins and needles), and also sensations arising from muscles, and giving the idea that the limbs are in a different position from that in which they really are,—in fact, all the sensations that pressure or some other cause of irritation may produce when applied to the ulnar or the sciatic nerves,—are often observed. In myelitis, some of these sensations always exist; in meningitis, or when there is simply a congestion of the spinal membranes, most of them are also observed, but less intense than in myelitis. In cases of irritation of the posterior roots of nerves by a tumour or a displaced bone, &c., referred sensations exist also. In such cases of irritation by a tumour, &c., and also in cases of congestion or meningitis, there is a feature which distinguishes these affections from myelitis: it is that in this last affection there may be a reference of sensations to all the parts of the body that receive their nerves from the part of the spinal cord which is below the upper limit of the inflammation, while in the three other affections the sensations are referred only to those parts of the body which receive their nerves from the part of the spinal cord at the level of the seat of the irritation. The non-inflammatory softening, a hæmorrhage, or a tumour in the grey matter (as long as they do not produce inflammation), and also the reflex paraplegia, are characterised by the absence of referred sensations.

"3rd.—*Feeling of Tightness round the Body or round the Lower Limbs.*—This sensation, which is so frequent in myelitis, exists also, sometimes, in cases of tumours, of congestion of the spinal cord, and in meningitis. It is absent in cases of non-inflammatory softening and of reflex paraplegia. From this last fact it results that the tightness across the chest or the abdomen, at the level of the upper limit of the paralysis, does not depend, as has been said, upon the effort made in

moving the paralysed parts by the non-paralysed muscles just above them. Another objection to this explanation is, that the same feeling which exists around the body exists also, sometimes, around the lower limbs, in myelitis. The most probable mode of production of this strange feeling is, that it is due to some irritation of sensitive nerve-fibres in the spinal canal producing a sensation referred to the periphery of the body (abdomen, chest, or limbs).

"4th. *Alterations in the Nutrition of Paralysed Parts.*—These alterations chiefly depend upon an irritation of the spinal cord or its nerves. It is principally in myelitis that they are observed. A rapid wasting of the paralysed muscles, the production of bullæ or sloughs over the sacrum, the nates, &c., are the most frequent results of an irritation of the vaso-motor or of the other nerves that have an influence upon the nutrition of the lower half of the body. These alterations are not observed in cases of reflex paraplegia, or of non-inflammatory softening of the spinal cord; neither do they exist in cases of hæmorrhage, or of a tumour in the grey matter, unless an inflammation is produced.

"5th. *Erection of the Penis.*—This is another symptom showing an irritation of the spinal cord or its nerves. It exists frequently at night, and sometimes in the daytime, in cases of myelitis or congestion of the spinal meninges. It is also observed, but less frequently, in cases of meningitis, of tumour upon the spinal cord, of hæmorrhage in the spinal canal (outside of the cord), and sometimes even in the reflex paraplegia, but then only on the introduction of a catheter or in consequence of some peripheric irritation. This symptom does not exist in cases of non-inflammatory softening, or of hæmorrhage or a tumour in the grey matter of the spinal cord.

6th. *Temperature of the Paralysed Lower Limbs.*—In those affections in which there is an irritation of the spinal cord or its membranes (congestion, myelitis, meningitis, pressure on the cord by effused blood, a tumour, or a displaced bone, &c.), the lower limbs, and especially the feet, are almost constantly very cold. This symptom is the consequence of the irritation of the vaso-motor nerves, which produces a contraction of the muscular fibres of bloodvessels, just as the irritation of the nerves of the muscles of the legs, feet, &c., produces cramps, twitchings, &c. In the reflex paraplegia the feet are also sometimes very cold, in consequence of a reflex contraction of their bloodvessels. In cases of non-inflammatory softening of the lumbar enlargement of the spinal cord, with a complete destruction of the vital properties of this part, the lower limbs are almost constantly very warm, as a result of the paralysis of the vaso-motor nerves.

"7th. *Degree and Extent of Paralysis of the Lower Limbs, the Bladder, and the Rectum.*—Of course great differences exist as regards the degree and extent of the paralysis, according to the degree and extent of the alterations in the spinal cord. We do not intend entering into any details on this subject. We wish only to say here that—1st, as regards the mode of appearance of the paraplegia, if it be sudden it is almost always due to hæmorrhage either in the cord or outside of it; 2nd, as regards the degree of the paralysis, it is equal in all the muscles of the lower limbs if the alteration occupies the whole of the lumbar enlargement or is above it, except in cases of reflex paraplegia, where some muscles may be much more affected than others; 3rd, as regards the changes in the degree and extent of the paralysis, they are rapid and frequent in cases of reflex paraplegia, of chronic meningitis with effusion, and of spinal congestion, while, on the contrary, they are slow and rare in cases of myelitis, tumours, and non-inflammatory softening; 4th, as regards the paralysis of the bladder and of the rectum, they exist more frequently in cases of myelitis, of non-inflammatory softening or of hæmorrhage in the grey matter, than in the reflex paraplegia, or in cases of tumour, of congestion, or even meningitis.

"8th. *Anæsthesia and Hyperæsthesia.*—Myelitis existing most frequently in the grey matter, anæsthesia (the different kinds of it, with the loss of the power of guiding the voluntary movements) is one of the ordinary symptoms of this affection. This symptom is less frequent or less intense in most other cases of paraplegia, except, of course, a hæmorrhage in the grey matter. As regards hyperæsthesia—*i. e.*, a morbidly increased insensibility—it is frequent in cases of incomplete paraplegia, when the posterior columns of the spinal cord, in a small part of their length, are destroyed, either by a tumour or by a softening (inflammatory or not).

"9th. *Reflex Power.*—In all cases of paraplegia in which the lumbar enlargement of the spinal cord remains uninjured, the reflex power of that enlargement increases notably. On the contrary, the reverse is observed in cases of alteration of this enlargement."

Mr HILTON'S Lectures on *Pain* are continued in the same journal. We make some extracts from this article.

"Some surgeons, when speaking of deep abscesses, say, with rash confidence, 'Plunge in a knife.' It is a grand term—'plunge a knife into a deep abscess.' It is an heroic, not a courageous plunge for the surgeon; for it is without danger to himself, but perhaps it is a fatal stab to the patient. Some more careful surgeons say, 'Wait until the abscess comes nearer to the surface, so that it can be opened without danger;' but the patient may die in the meantime. Now the plan I have been in the habit of adopting and recommending is this—for example, in the case of opening a deep abscess in the axilla,—cut with a lancet through the skin and cellular tissue and fascia of the axilla about half or three-quarters of an inch behind the axillary edge of the great pectoral muscle; at that part we can meet with no large bloodvessel. There is only a small branch of one of the external thoracic arteries, which sometimes runs along the edge of the axilla; excluding that, which if wounded can be easily ligatured, we run no other risk, so far as I can see. Then push a grooved probe or grooved director upwards into the swelling in the axilla; and if you will watch the groove in the probe or director as it is being passed up through the comparatively healthy tissues into the axilla, a little stream of opaque serum or pus will show itself. Then take a blunt (not a sharp) instrument, such as a pair of 'dressing forceps,' and run the closed blades along the groove in the probe or director into the swelling, and by opening the handles you at the same time open the blades situated within the abscess, and so tear open the abscess; and, lastly, by keeping the blades of the forceps open during the withdrawal of the instrument, you leave a lacerated track or canal, communicating with the collection of pus, which will not readily unite, and which will permit the easy exit of the matter. In this way you may open an abscess deep in the axilla, or in other important parts of the body, without fear of inflicting any injury upon the patient. Having been connected many years with a large hospital, I have necessarily had good opportunities of trying this method. I have not opened a deep abscess during that time in any other way, and I can say, honestly and truly, that it has never failed, and that I have never observed any inconvenience from it.

"A curious coincidence happened to me with respect to this method of proceeding. I was requested some years ago to see a surgeon in London, who was suffering from a large inflammatory swelling in the arm-pit, resulting from a wound made at a post-mortem examination. When I saw him, he was quite typhoid; he had a dry, brown tongue, and he was delirious. His pulse was very feeble, and there were other circumstances indicating impending fatal mischief. I opened the abscess in the axilla in the way which I have pointed out, passing the grooved director between two and three inches up into the axilla, and opening the abscess by a pair of dressing forceps. The patient got well, the starting point of his recovery being the opening of the abscess. About ten years afterwards, this same surgeon came to me one morning, in a great hurry, to request me to go with him immediately to see a patient who was dying. He then told me that on the previous afternoon he had opened an abscess in the arm-pit. 'I did it,' he said, 'without any difficulty, as well as possible, for I used Liston's knife' (blaming the poor knife for what had happened). 'I opened the abscess yesterday, and let out the matter, and this morning I find the arm-pit fuller than before it was opened, and blood is coming out of the hole I made. The man is nearly dead, and his arm is as big as two.' We went directly and found the man nearly at the point of death from loss of blood. I had to enlarge the aperture in the axilla, so as enable me to introduce my hand, and scoop out the whole of the blood, and to expose the cavity to the external air. No further hæmorrhage occurred, but the patient was very nearly killed. Now, this was the very same surgeon whose axillary abscess I had opened with the dressing forceps high up (two or three inches from the surface), without doing him any mischief. He, with 'Liston's knife,' wounded a bloodvessel in the arm-pit, which led to the patient's fearful danger.

"*Orbital Abscess.*—Some years ago I had in Guy's Hospital a patient with a fractured base of the skull, the fracture extending across the posterior part of the orbit. After some little time the parts within the orbit began to swell, and the eye to be protruded. The patient was amaurotic on that same side, and was suffering locally as well as constitutionally very severely. With the hope and probability of finding a collection of blood or pus at the deeper part of the orbit, I made, with a common lancet, a small cut horizontally through the fibres of the orbicularis palpebrarum of the upper eyelid, and passed through it a grooved probe or director along the roof, towards the apex of the orbit. A little purulent fluid was visible in the groove of the director. I then introduced along the groove the blades of a small pair of dressing forceps, and opened an abscess by separating the handles of the forceps; the matter escaped freely, the patient was relieved of his distress, the pressure upon the optic nerve was thus removed, the amaurosis disappeared, and he ultimately recovered without further aid.

"*Deep Cervical Abscess.*—About four or five years ago I was sent for by a surgeon in my neighbourhood to see his wife. She was a delicate woman, in about the mid-period of pregnancy, and it was feared that she would miscarry in consequence of having a large inflammatory, painful swelling deep in the right side of the neck. There was an obvious fluctuation in the swelling, and it was thought to be an abscess. She was suffering greatly, and the question was, how to reach the seat of the disease. I should not have dared to put a knife in, because, with all the anatomical accuracy which a surgeon may possess, it must be admitted that movable parts get very much displaced by the enlargement of an abscess, so that it is not possible for the best anatomist to tell with accuracy the exact position of those bloodvessels and nerves which it is important to avoid. I cut through the cervical fascia with a lancet, thrust into the swelling a grooved probe, and used the dressing forceps. In this way the abscess was opened, and the patient did perfectly well. This was the case of the wife of a surgeon, who saw the difficulty of opening the abscess, and who appreciated the advantages of this safe method of proceeding."

Instances of a Post-pharyngeal Abscess, an Iliac Abscess, Sub-gluteal Abscess, and thus opened, are related, and the Author concludes thus:

"*Sub-fascial and Sub-muscular Abscesses.*—I have pursued this same safe plan over and over again in sub-fascial or sub-muscular abscess or abscesses formed upon or under the periosteum in the thigh. It has occurred to me many times in such cases, after dividing the fascia lata, to see the healthy muscles stand up boldly and clearly in the wound; and, instead of cutting through them, I have reached the abscess by running a director right through the muscles into the collection of fluid, and then introducing the dressing forceps in the way I have described. It is, I believe, impossible that any surgeon can foreknow the exact position of the descending branches of the circumflex arteries, or perforating arteries of the profunda, in a case of deep abscess of the thigh; so that when he plunges his knife into the deep swelling, he can feel no certainty as to his being able to avoid bloodvessels or nerves. But if the plan which I have recommended be pursued, it is hardly possible that any such mischief or accident can occur; and I can add this satisfactory assurance, that I have not yet had a single case in which this method of opening deep abscesses has been followed by important hæmorrhage.

"I have recently (October, 1860) seen a young patient who a short time since had a deep abscess in the thigh, just above the knee-joint. The surgeon in attendance opened the abscess by some

kind of cutting instrument. Pus and arterial blood escaped from the opening, but the bleeding was stopped for a time by plugging the wound. A recurrence of sudden and profuse arterial hæmorrhage took place in a few days, which nearly destroyed the patient. It was then thought right to ligature the femoral artery at the upper third of the thigh, and the bleeding ceased from that time.

"In the case of a patient having an abscess close upon the interosseous ligament in the forearm, if the attempt to reach it be made by cutting down upon it, it is extremely difficult, next to impossible, to ascertain previously the exact position and direction of displaced nerves, veins, or arteries; so it must be equally impossible, with certainty, to avoid wounding some of these important parts. But if you simply cut through the fascia so as to expose the muscle at the most prominent point of the swelling (taking care to avoid the course of the larger bloodvessels, which may be felt with the finger), and then thrust the grooved director through them down to the interosseous ligament, the matter will show itself by welling up the groove of the director, and the introduction of a dressing forceps will then complete the operation with safety.

"I think I have now said enough of this operation. I have not brought it forward from any egotistical feeling, but simply for the purpose of showing in what manner deep abscesses may be opened with the greatest safety."

Dr Brinton's Lecture on Physiology is continued this week in the same judicious spirit; and Mr Horace Swete of Somerset reports a case of *Gunshot Wound of the Face*, causing the destruction of the greater part of the lower jaw.

The 'Medical Times and Gazette' contains a continuation of Dr Simpson's Lectures on the *Diseases of Women*. This treats of puerperal insanity in connection with albuminuria. He lays down the following propositions:

"*a.* That albuminuria precedes and attends the first access of puerperal insanity in a large proportion of cases; but perhaps not so frequently and so constantly as it precedes and attends upon attacks of puerperal convulsions. I have found it present, in eight out of ten cases of puerperal insanity, at the commencement of the disease; and possibly it escaped observation in these two cases from not being looked for sufficiently early in their progress. For it seems to me,

"*b.* That the coagulability of the urine in puerperal insanity generally disappears within a short time after the attack commences, and hence disappears more speedily than happens in puerperal convulsions. The fire of disease goes on burning in these cases of insanity after the lighted match is merely applied, and the strange morbid clockwork runs on, as it were, after the key that wound it up is withdrawn. I have seen all traces of albuminuria in puerperal insanity disappear from the urine within fifty hours from the access of the malady. The general rapidity of its disappearance is, perhaps, the principal, or, indeed, the only reason why this complication has escaped the notice of those Physicians among us who devote themselves with such ardour and zeal to the treatment of insanity in our public asylums. As another proposition let me state,

"*c.* That when the puerperal insanity recurs in the form of successive attacks or explosions, each attack may be found connected with a new attack or advent of albuminuria. In one of the first cases in which I had occasion to watch the connection of puerperal insanity with puerperal albuminuria, two accesses of mania came on, both very suddenly; and the last of them proved ultimately fatal. Between the two attacks there was an interval in which all symptoms of any mental disorders were completely absent. The first urine passed after the access of each paroxysm was highly albuminous. During the intervals between the two attacks it lost all tendency to coagulate under either heat or nitric acid.

"Puerperal convulsions, which, as I have said, are almost invariably connected with albuminuria, are often attended—particularly when very severe in their character—with some temporary degree of incoherence, delirum, or stupefaction; but they rarely, as far as I have seen, terminate in true and established puerperal insanity. Dr Churchill, however, states that he has seen puerperal insanity accompany or follow puerperal convulsions in more than one case; and instances of the same kind are alluded to by Drs Reid, Merriman, Gooch, Esquirol, and others. Dr Ingleby seems to have noticed, in repeated examples, the lapse of puerperal convulsions into mania. In his essay on 'Puerperal Convulsions' he observes, 'I am acquainted with several cases of puerperal convulsions which were succeeded by puerperal mania; the transition (he adds) might probably be the result of the large bleedings which were necessary to subdue the primary disease.' We have a more simple and certain explanation of the connection between them in the pathological fact, that both are found to be dependent upon, and in some way or other connected with, the pre-existence of albumen in the urine. But if you ask me, further, How does the presence of albuminuria in the urine account for the supervention of either puerperal convulsions or puerperal mania? and more particularly, How can it originate two such diverse morbid states as convulsions and insanity?—then in answer I can only, I fear, confess my ignorance of the probable or possible rationale of the problem. Pathological Chemistry must make very great progress, ere we can hope to solve perfectly any such deep pathological riddles. The mere presence of a great amount of albumen in the urine does not in itself afford any explanation of the result, because the loss by excess of a far greater amount of albumen from the mass of circulating blood would produce no special effects or results upon the nervous system. But the presence of an excess of albumen in the urine is usually accompanied with other and far more important changes directly in the chemistry of the renal secretion, and indirectly in the chemistry of the blood itself. When albuminuria exists, there is always liable to accompany it a diminished elimination of the urea, and perhaps of other excrementitious matters that pass off by the urine; and, consequently, there is a corresponding retention within the circulating system of these effete substances that should be duly and systematically thrown off by the action of the kidneys. Urea when thus, or when otherwise, accumulated in morbid excess within the circulating system, does not, according to the observations and experiments of Frerichs and others, produce any very special intoxicating or poisonous effects upon the nervous system, merely *per se*, or simply as urea. But the accumulated urea is apparently liable to decompose and become altered under varying influences into various new organic compounds within the body, some of which, like morphia, strychnine, coniine, and other vegetable alkaloids, produce different diseased states, by exerting different toxicological effects upon the cerebro-spinal and other systems. Dr Frerichs holds that the mere simple and common decomposition of the accumulated urea into carbonate of ammonia is the cause of albuminuria ending in convulsions and coma. Urea, as urea, does not, in his opinion, and according to his experiments, produce convulsive and comatose effects; but these effects are produced by a sudden excess in the circulating system of carbonate of ammonia, a salt which urea readily forms when it becomes decomposed. But when the whole constitution and chemistry of the blood becomes deranged and altered by the sudden accumulation of the excrementitial materials of the urine within it, as is always liable to happen in puerperal albuminuria, other organic toxicological agents may become developed within the system from the decomposing urea or other components of the urine—possibly some of these newly-formed products or agents of an *alkaloidal* character—and one or other of which may be as certain of exciting delirium and insanity, as an overdose of morphia or brucine, or other poisonous vegetable alkaloids, is certain of exciting their special toxicological effects upon the economy. Mr Calvert and other chemists have lately found organic alkaloids of various, and most of them of still unknown, types, formed during animal decomposition. In the blood of the puerperal female,—greatly modified as it is in the normal states of pregnancy and delivery, and containing as it does after parturition the effete elements of the involving or disintegrating uterus, and the materials for the new lacteal secretion,—ferments and agents may possibly exist, which are more apt to develop special morbid poisons out of the retained renal excretions than happens in other states of the system. But I repeat, the whole subject is yet quite dark and conjectural, and will remain so till pathological chemistry is able to cast some light upon it."

The Author then states that, like puerperal convulsions, puerperal insanity occurs most frequently in first confinements, and that it is often produced by mental emotions, instances of which he cites. On the semeiology of the disease, he remarks:

"The forms which insanity usually assumes in the puerperal female are those of mania and melancholia—most frequently the former. But there is nothing special in the character or symptoms of puerperal insanity as distinguished from other forms of insanity. The symptoms, when the disease is established, are simply those of common mania or common melancholia, or of some intermediate type of mental disorder. Before the attack the patient is usually for a time restless and irritable, and does not sleep. If you have a puerperal patient complaining of great or total want of sleep, watch her narrowly and anxiously; for she may speedily lapse into insanity. If, in addition to this wakefulness, you discover the urine to be albuminous, the probability of insanity impending over her becomes only the greater. The first suspicious symptom of the actual disease generally consists in some oddity of thought, or of expression, or of affection. I lately saw a case in the country where the patient's insanity began with her insisting upon her Doctor, at one of his visits, baptising her infant. She is markedly different in some of these points from what she is naturally. She begins betimes to utter nonsense, or to talk very volubly, and falls at last into a state of complete delirium, when, unless she be constantly watched, she may make some unhappy attempt on her own or another's life. Or, again, the patient may begin by being low-spirited and dull, refusing her food, and taking no interest in her offspring, or even showing an aversion to it; she takes an unreasonable and unnatural dislike to her husband, her nurse, or her medical attendant: or harbours peculiar suspicions regarding them or regarding her food, fearing that she is to be poisoned or otherwise killed, and gradually settles down into a state of confirmed melancholia. The remarks I have to make regarding the prospect of the patient's recovery, and the means of treating the disease, I must reserve for another opportunity."

Mr Le Gros Clark's Clinical Lectures are continued in the same journal.

We quote the following on *Fissure of the Rectum*:

"I have recently admitted a patient (on whom indeed I am going to operate to-day), suffering from a complaint which is so often misunderstood, and therefore mistreated, that I am glad to take this opportunity of directing your attention to the case. The patient is a respectable middle-aged female, who was sent up to me to undergo the operation for fistula. In reply to my inquiries, she stated that she had no external wound, but that some discharge came from the bowel; that she was comparatively easy, except when the bowels acted and for some time afterwards: at these periods, she said, the pain was agonising, and that her medical attendant supposed there must be some disease at the lower part of the spine. Before examining her, I felt pretty sure of the nature of her complaint, and found, as I expected, a fissure in the rectum. She had endured this suffering for two years.

"I have treated many cases like this one in the way I will presently describe, and with invariable success, where the fissure is uncomplicated with other disease. The suffering of the patient is alone almost sufficient to characterise and identify the malady. It is described as being, during defecation, of a lacerating, stabbing, or burning nature, and so acute as to be almost intolerable when the evacuation is solid. I have known the pain spoken of in the most exaggerated language, and suggest the impression that there must be some serious disease, such as scirrhus in the bowel, or inflammation of the prostate gland, or, as in this case, disease of the coccyx or womb. Many of you heard this patient's remark, to the effect that she is the mother of thirteen children, and 'would rather go through the suffering of parturition than pass a

confined motion by the bowel!' On examination in these cases, the sphincter is found spasmodically closed, from the dread the patient has acquired of allowing the bowels to be stretched at its lower part: this I have known to be mistaken for stricture of the rectum. On introducing the fingers with caution, the patient at once complains of the characteristic suffering; and, on feeling the circumference of the bowel just above the anus, a longitudinal groove or fissure will be felt, situated almost invariably at the back part, on or near to the median line. A practised hand readily detects this shallow cleft; but, if desirable, it may be easily seen with the aid of a speculum. I have treated these cases with various forms of caustic, yet ineffectually; but the operation with the knife is simple, productive of very little pain, and almost infallible. The knife I use has a straight, narrow, button-pointed blade, which is introduced, on the flat, along the palmar surface of the forefinger as it rests within the rectum, the patient leaning forward over the back of a chair or on a bed. The edge of the knife is then turned backwards, and, as it is drawn out, the whole of the fissure, to the extent usually of about an inch, is divided to the free margin of the bowel. This incision should cut through the muscular fibres encircling the gut, close to or at the fissure. But little bleeding follows, and no dressing is required. The bowels should be freely cleared out on the day before, and then kept at rest for a couple of days. A good deal of smarting pain is felt for a few hours, and the first act of defecation is painful; but after that all pain usually ceases, and recovery speedily follows.

"This condition of the bowel is analogous to a similar condition of the lower lip, to which many persons are subject, especially during the winter months. The fissure being established, it is perpetuated by the constant action of the annular fibres of the intestine upon its margins; and this cause, co-operating with the passive distension at each act of defecation, prevents the part from healing, and induces that spasmodic constriction which is always more or less noticeable in the external sphincter. On this explanation the treatment is founded, the object being to keep the fissured part at rest by division of the annular fibres, including the inner margin of the external sphincter; and this may be accomplished without risk, on account of the ulcerated cleft being, usually, at the back part of the bowel."

Mr ZACHARIAH LAWRENCE contributes an article on the *Utrecht School of Ophthalmic Surgery*, and Dr BENJAMIN HOBSON continues his article on *Medicine in China*. It appears that the theoretical views of the Chinese resemble those propounded by Hippocrates, though their practice differs. They speak of the human body as made up of five elements—earth, wood, water, fire, and metal (the air is excluded)—which have relation to the five solid viscera (the brain is excluded), which again have relation to the five planets, the five tastes, and the five colours. Between these there is a suitable harmony and connection. Medicines are classed under one of these five elements. They also believe in dual powers of nature, called yin and yang. Some passages are curious as exhibiting manners in China: for instance—

"Such persons of independent judgment and keener powers of observation than their fellows, not unfrequently rise to considerable celebrity and wealth. I heard of one well known in Canton, nicknamed Tawang Seen-shang, or Dr Rhubarb (from his frequent use of this medicine and his great faith in its remedial powers). He and some others that I could name were engaged from morning to night in medical practice. They would keep at home prescribing for the sick until a late breakfast hour; after ten they would commence going their rounds in the sedan chair, carried with great haste by three or four men. Those patients were visited first who had their names and residences first placed in the entry book, and as the streets were narrow and crowded, to avoid trouble in finding the house, a copy of the Doctor's sign-board would be pasted up outside the patient's door, so that the chair-bearers should be able to recognise the house at once without delay. The Doctor being ushered into the hall or principal room, is met with bows and salutations by the father or elder brother of the family. Tea and pipes are offered in due form; and he is requested to feel his patient's pulse: if a male, he sits opposite to him; if a female, a screen of bamboo intervenes, which is only removed in case it is requisite to see the tongue. The right hand is placed upon a book to steady it, and the Doctor, with much gravity and a learned look, places his three fingers upon the pulsatiog vessel, pressing it alternately with each finger on the inner and onter side; and then making with the three fingers a steady pressure for several minutes—not with watch in hand, to note the frequency of its beats, but with a thoughtful, calculating mind, to diagnose the disease and prognosticate its issue. The fingers being removed, the patient immediately stretches out the other hand, which is felt in the same manner. Perhaps a few questions are now asked of the father or mother concerning the sick person; but these are usually few, as it is presumed the pulse reveals everything needful to know. Ink and paper are produced, and a prescription is written out, which consists of numerous ingredients; but there are one or two of only prime importance, the rest are servants or adjuvants. They are all taken from the Vegetable Kingdom, and are mostly simples of little efficacy. The prescription is always taken to a druggist to be dispensed, the prescriber never makes up the medicines himself, and as large doses are popular (*a quid pro quo*), so the decoction made from the whole always amounts to pints or even quarts, which are swallowed in large potions with the greatest ease; powders, boluses, pills, and electuaries are also used. If the patient is an officer of the Government or a wealthy person, the nature of the disease, prognosis, and treatment are written out for the inspection of the family; for this the Doctor's fee is a dollar, about 5s.; but, generally speaking, both the Doctor and the patient's friends are quite satisfied with a verbal communication, and if the man has a gift for speaking, and has brass enough to use it to his advantage (both of which are seldom wanting in time-serving men), he will describe with a learned and self-satisfied air the ailment of the patient, and the number of days it will take to cure him. The fee is wrapped up in paper, and called 'golden thanks,' and varies from 6d. to 2s. 6d., or more, according to the means of the patient; the chair-bearers being paid extra; the Doctor returns to make another visit, if invited, but not otherwise. It is more common, if the patient is not at once benefited by the prescription, to call in another, then a third, then a fourth, and even more, until tired of Physicians (for the Chinese patience is soon exhausted, and their faith by no means strong in all their Doctors' asservations) they have, as a last resource, application made to one of the genii, or a god possessing wonderful healing powers. The result is, that the patient dies or lives not according to the treatment received, for that must be generally inefficacious, but according as the natural strength of the patient is equal to surmount the difficulties by which he is surrounded."

Dr Hobson found in a Chinese Materia Medica a list of 442 medicinal agents. The list is detailed: we shall not, however, extract it, but give the Author's comments.

"Many of the medicines cannot be discovered from being in a dried state, and from only a portion of the plant being obtainable. They are imported from all parts of the Empire, from Japan, Siam, and the Straits, and form an important and lucrative branch of trade.

"The first treatise on Materia Medica in China is attributed to the famous Shin-nung, who lived in the traditionary period of the Chinese Chronology, who is spoken of as the Father of Husbandry and Medicine. The present Pun-tsaoo, or Chinese Herbal, contains upwards of a thousand different medicinal herbs, fruits, seeds, parts of animals, and mineral substances; but while it is rich in warm vegetable stimulants, carminatives, stomachics, and astringents, it is greatly defective in pharmaceutical preparations, as mineral oxides, acids, salts, tinctures, &c. The Mineral Kingdom supplies, as we have seen, but a very small part of the whole, which no doubt arises from the ignorance of chemical combinations, and the influence which gases, acids, and alkalies exert upon one another, both in the Vegetable and Mineral Kingdoms. The composition of the simplest compound bodies is unknown; what we know to be the compound they regard as simple bodies. The utmost surprise is expressed when told that gases, in certain proportions, constitute our atmosphere and water. The Chinese have no names for gaseous substances. Ke, which means air or breath, comprises them all. When composing a work on pneumatics, names had to be found for oxygen, nitrogen, hydrogen, carbonic acid, &c. Nothing appeared known concerning the existence of gaseous bodies, and still less of their composition and peculiar properties; and, from the same cause, the air-pump, barometer, thermometer, electric and galvanic machines, had not only to be explained, but names invented before they could be described. The same applies to radiation of heat, solar light, optics, and other branches of natural science, which are all yet in their infancy in China. The properties of medicines as aperient, anthelmintic, alterative, astringent, demulcent, diaphoretic, &c., are understood, and are easily explained; but, owing to the entire absence of chemical knowledge, there is at present an almost insuperable difficulty to give them, in an easy and intelligible manner, the composition of bodies. The analysis given above will show most of the principal medical agents in use. It will be less limited, in proportion as China drops her exclusiveness. Our Materia Medica, we know, is extremely rich and valuable, because it is made up not only from the well-known natural or artificial products of our own country, but is added to and improved by the admission of most useful medicines from other countries. For example—our rhubarb and musk from China, our opium from Turkey, our camphor and spices from Singapore, our aloes from the Cape of Good Hope, our cinchona from South America, and various other products from all parts of the world, so that, if these supplies were cut off, British Physicians would scarcely be able to write a prescription suited to the varied complaints they meet with at the present day. The Chinese Doctors, however, do write prescriptions, and their patients do take a great deal of physic (homœopathic doses would not answer); but I have been told, again and again, by the prescribers, that they keep their list within 100 drugs, and even fewer, for all diseases, they having no faith in more than one-tenth recommended in their books. When Medicine is really studied as a science in China, and the true nature of diseases begins to be understood, they will need the infusion of new and well-tried remedies from Europe in their Pharmacopœia. I will mention a few things that they need. These are the mineral acids, ether, a proof spirit for tinctures (their own spirituous liquor, prepared from rice, is too weak to dissolve camphor), aloes, ammonia, ammoniacum, nitrate of silver, belladonna, good calomel (the Chinese use an impure preparation, which is not to be depended upon), cinchona (quinine is now much valued, and would be generally sought after if it were less expensive; it sells there for £1 per ounce), cod-liver oil, copaiba, ergot, carbonate of iron, soda, magnesia, ipecacuanha, acetate of lead, carbonate and sulphate of potash, quassia (for its cheapness; they have a red and yellow gentian, but it is dear compared with quassia), turpentine, jalap, croton-oil (they have the seeds, but not the oil), iodine, hydrodate of potash, hyoscyamus, squill, sulphur (because of the frequency of scabies, and the greater cheapness of the imported article), preparations of antimony (the metal, though so common in Borneo, is unknown in China), and of zinc, and its valuable preparations. These, and several others, I have named and described in a work on Medicine, and in course of time I hope they will be added to their own improved Materia Medica; that at present is a curious medley, and little good could arise to us from a translation of it into English. I will allude only to human milk as a good medicine for old people! Their books say 'that its taste is sweet, and that it nourishes the viscera, is a soothing application to abraded skin and inflamed eyes, and fattens old, decayed persons. Its virtues surpass considerably cows', goats', or mares' milk. Formerly some toothless old men, who took human milk, lived on a hundred years, became fat, had good spirits, renewed their youth, and begat children.' The wonderfully nourishing properties of women's milk to aged persons is not, unfortunately, confined to books, it is generally believed by the common people; and in one instance I saw the ill effects of this dangerous error. An infant, a few months old, in consequence of the mother being unable to continue nursing, was committed to a Chinese wet-nurse; and as money was no object, the woman that had the best supply of milk was chosen for this purpose. For a few days the child seemed to go on tolerably well, but it soon became affected with head symptoms; and as one child had died a year before from symptoms somewhat similar, the parents became alarmed, and begged that I would come in, in consultation, to see the child. I found the child lying listless and almost insensible on a friend's lap, labouring under the symptoms so graphically described by Dr Marshall Hall and Dr Watson, of spurious hydrocephalus. I examined the nurse, who was a young healthy-looking woman, with breasts full of milk to overflowing. I had some put in a cup for inspection; it threw up no cream on its surface, and looked pale and watery. On farther investigation I discovered that the woman had been in the habit of selling her milk by small cups-full to old persons, under the idea of its highly nutritive properties; and thus her milk, though abundant in quantity, soon became quite degenerated in quality; and instead of being nutritious, was actually poisoning the child dependent upon it, and now fast sinking from inanition. I recommended the nurse to be changed immediately. Happily a suitable one was found in

(Continued at Page 328.)

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Untamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B — The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

THE MEDICAL CIRCULAR.

WEDNESDAY, NOVEMBER 14, 1860.

THE TURKISH AND ROMAN BATHS.

When Priessnitz invented the Hydropathic system, he had no foresight of the development which the principle of the Water-cure would attain. The palaces of Moor House and Malvern were never outlined in the phantoms of his heated fancy. English facts, however, always surpass German imagination. If the faculty of imitation be denied to us, that of development is certainly in conspicuous strength. The seed that perishes in Germany, or grows at most to the dimensions of a stunted shrub, in England expends into a goodly tree; and though it should distil poison, we never fail to regard the culture with admiration. Here, indeed, our natural energy, resources, and freedom of action enable us to produce the best specimens of even the worst things. So Hydropathy has enjoyed the advantage of our wealth and liberty; and whilst it has ceased to be the curer of all diseases, it has become the business of the indolent, the delight of the satiated, the hope of the desponding, and the relaxation of the overworked. Men who fancy themselves ill fly to it for a remedy, and those who are incurably sick deceive their fears with its illusions. This is, indeed, something, but not that which Hydropathy originally professed to be.

The vast pretensions set up for the Water-cure led reasonable people to consider that, though those pretensions might be exaggerated and fallacious, yet the sanitary virtues of cold water had not been so much esteemed by the English people as they deserved. The uses of water in cleansing the skin, purifying the body, and making the home decent, were soon acknowledged, and societies of philanthropic men exerted themselves to establish Baths and Washhouses in the various towns of the Kingdom, where the poor man and the artisan could, for a small sum, obtain a daily bath if they pleased, and be provided with ample accommodation for all the laundry-work of the family. Thanks to Lord Shaftesbury and his friends, these institutions have been a great blessing to the community. The health of the people has been increased by the accommodation they have afforded, and domestic cleanliness and comfort are now possible in the homes of the poor.

The movement, however, has not stopped at this point. Through the activity and public spirit of Mr Kelly of Liverpool, Drinking Fountains have been everywhere established, and one of the most shameful evils of our towns, that of dram-drinking, has been thus assailed. It will take many years for the antidote to work a cure. The vice has eaten deep into our social system, and in innumerable instances it has gone, doubtless, beyond the power of any human remedy. But we are not without hope that the facilities now provided for the assuagement of a working man's thirst with the Samaritan blessing, a cup of cold water, will foster a habit of sobriety among the rising generation, and redeem the character of our people. The beer-shop and gin-palace are undermined, and time will bring about their downfall.

Recently, however, a new phase in this sanitary movement has taken place. Our readers must have perused the vigorous letters published in this Journal, by Dr Tucker of Sligo, on the subject of the Turkish and Roman Baths; and he is only one of many who are now labouring to institute a more complete system of Bathing in this country, and who have taken the ancient Roman or the modern Turkish bath as a model. There is some question as to the individual who has the right to be considered the author of the new system; some persons extolling the claim of Mr Urquhart, who has advocated the Turkish plan, and others that of Dr Barter, who has adopted the Roman system. This dispute is unimportant; for, in reality, these systems of bathing, modified in various ways, have long been in use in this country, but have been confined to the accommodation of the wealthy. The writer of this article many years ago submitted to a regimen of vapour-baths, cold douches, shampooing, and cups of coffee, and suffered an attack of cynanche tonsillaris as the reward of his intrepidity.

There is an effort now in operation to make these Baths universal, and to bring them within the means of the humblest of the people. The idea is not new; it must have occurred to most men who have taken an interest in the establishment of Public Baths; but the public effort and the general aim are of recent date.

Is there any reasonable objection to the establishment of such a system of Bathing? There are many persons who will think that the introduction among us of the most remarkable characteristic of the days of Roman degeneracy and of modern Turkish sloth will inevitably lead to, if it be not already the exponent of, a luxurious and enervating civilisation. We have no such fears. If the establishment of such Baths indicate a present deterioration of national character, the fact is so, and the Baths are not to blame: but this we do not believe, any more than we apprehend that they will in future exercise an injurious influence upon the moral excellence and physical hardihood of our fellow-countrymen. We believe that we shall know how to use without abusing such an efficient means of increasing bodily comfort and improving health.

It would be easy and not expensive to annex two or three chambers to the existing Public Baths, in order to give effect to the system. They are now provided with warm baths and plunging baths; why should they not be supplied also with the means of giving their customers a douche, a shower-bath, or a vapour or hot-air bath, as may be required? The warm bath is, from a sanitary and remedial point of view, one of the least useful of all these modes of bathing; and yet it is the only one to which our countrymen are in the habit of resorting. The hot-air bath is, according to the testimony of those who have tried it, superior to the others; and yet such a bath is with difficulty obtained. If a thing be done at all, it is worth doing well; our Bathing system is yet only half done, and will not be complete without these additional arrangements.

Is the prospect too grand to be conceived of a Bathing Establishment in every town, after the old Roman model, with its frigidarium, tepidarium, and sudatorium, having also a restaurant attached—on cold-water principles, of course—and a public library with class-rooms for students, and elegant gardens, wheresoever possible, for a promenade? Might not the Directors of the Crystal Palace establish such an institution, with advantage to their own coffers and benefit to the public? We have no doubt that it would be successful, and that a great impulse would be given to the cause.

The habits and conditions of town-life almost necessitate institutions of this nature for the preservation of the health of the people. A man who takes abundant exercise in the pure air of a mountain-side, whose very toil is cheered by the sun and braced by the wind, whose blood is rapidly decarbonised by the free contact of the atmosphere with its deteriorated elements in every corner of his permeable and spacious lungs, whose skin acts with freedom, and maintains an active supplemental oxygenising function, whose brain is not overtaxed with work, and whose physical labours are rarely more than recreative,—such a man may not require the use of artificial modes of restoration. But our town-life is itself artificial. The pure air of heaven is unbreathed, and the glowing beams of the sun unfelt, by tens of thousands who tend engines in underground cellars, or work in the gas-light, who sew and weave in fetid garrets, or measure silks and woollens in shops and warehouses close with animal exhalations and unilluminated by the direct rays of the

sun. Neither the lungs, nor the skin, nor the muscular system of such persons discharges its proper functions, and disease is quickly established. The undilated pulmonary organs soon become the habitat of tubercle; the skin, covered with layers of effete epidermis, casts additional duty upon the kidneys, and becomes itself subject to noisome diseases; the kidneys, in their turn, degenerate, and premature death is established as a law of humanity. Extreme cases require unusual remedies. Believing that a more perfect and general system of Bathing than that now in use would be beneficial to the denizens of towns, we hope that the attempts now made may meet with encouragement and success.

SUMMARY OF THE WEEK.

"BAD TIMES" FOR DOCTORS.

We heard a Surgeon in full practice assert the other day, that he had not sent out a chalk mixture for the whole summer. We do not know how this phenomenon could be accounted for, unless it be that there have been no diarrhœas. This inference appears to have been correct; for not only in the practice of our Metropolitan friend, but throughout the country there has been, as we are informed by the recent Quarterly Report of the Registrar-General, an extraordinary diminution of the ordinary diseases of the season. The perpetual rains have made England very uncomfortable, but exceedingly healthy. An Englishman is by nature amphibious, and a deluge above and below agrees with him. His bodily energies are nourished by imbibing atmospheric moisture, and he fattens upon a fog. Let us hear no more slanders against November weather. The suicides about this time of the year have more to do with the anticipated quarter-day and Christmas bills than the gloomy condition of the atmosphere. The Registrar-General's returns make this apparent. There never has been such an excess of births as during the last quarter, never so small a number of deaths. Diarrhœa disappeared with last year's sunshine; and Mr Leigh of Manchester sagely remarks, that the absence of diarrhœa and the coincident abundance of fruit prove that diarrhœa is not caused by the latter, but by heat. The constant rains have swept all pollution into the sea; our streets have been kept clean, our drains wholesome, and even our Metropolitan river has relinquished its historical character. Pure breezes have wooed its embraces, and salmon have come as far as Erith to pay it a visit. It has been possible to eat whitebait at Blackwall without being stifled by heat or asphyxiated by carburetted hydrogen, and the health of Aldermen and rich citizens has been the better for it. Legislation, too, has been agreeable business; no complaints of foul gases have been heard, and the House had a very long Session. No wonder our Premier was in such a good condition for an autumnal tour, and that Sir George Lewis looks so surprisingly cheerful. The Doctors are the only members of the State that have good reason to be gloomy. If this weather continue much longer, their occupation will be gone, and Homœopathy will be in the ascendant. The lustration which the earth has undergone must have cleansed it of all miasmatic germs, and there is every probability that the present quarter will be as salubrious as the past. The weekly reports of the Medical Officers have, at any rate up to this time, given us an assurance that this happy state of things will continue. Our brethren are fortunate in having nothing to do, and we advise them to make the most of their leisure by chartering the Great Eastern and making an excursion in a body to see the siege of Gaeta. If they would prefer a trip to Pekin, and a kotow before his Celestial Majesty, they will have plenty of time to get there and back before the next epidemic. We will take care to give them due notice of the first signs of the disease-mist in our atmosphere.

When the frozen-out gardeners appeal to public charity next year, we have no doubt that they will meet with unusual sympathy from the members of the Medical Profession.

THE MEDICAL SOCIETY OF LONDON.

Is the practice of Medicine to be divorced from the theory of it, and scepticism and speculation to chase venerable experience out of the field? Why is it that the papers read this Session at the old and honoured Medical Society of London, hitherto the favourite arena of practical men, have been generally on abstruse or novel subjects in animal or general chemistry, only incidentally and by courtesy applied to the professed pursuits of the Fellows of this Society? We hope the Fellows will consider the interests of the Society, and stay this flood in time. If certain of the Fellows desire to make their inquiries through the medium of the Society, let it be done through a new Physiological Section, which might be advantageously created. But do not occupy the Weekly Meeting with speculations on which no Fellow can give an opinion. The debates, which are the soul of a Society of this nature, are on these occasions literally extinguished; and all that passes is a series of brief and modest questions, eliciting long and often obscure answers. The Fellows are getting tired of this practice, and unless a different course be taken the Society will suffer serious injury. Let the papers be shorter and more practical, and the debates, instead of being languid, will be as animated and useful as of yore.

MORE ARSENIC-EATING.

The Manchester Philosophical Society has been entertained with a disquisition by Professor Roscoe on the arsenic-eating practice of the Styrian peasants. Anxious to determine the truth of the statements that have been made, he communicated with his friend Professor Pebal of Lemberg, who supplied him with copies of seventeen letters which had been addressed by as many Medical men to the Government Medical Inspector at Gratz. It seems, however, that whilst all these gentlemen alleged that the practice existed, many of them had no personal knowledge of it, others described certain cases which they had been "told of by trustworthy persons," whilst others actually report upon cases they had seen. Of these three orders of witnesses, the first are mere gossips, the second a mere circumstantial variety of the first, and the third must either be honest men or dupes. Let us see. Now we are told that "the most narrowly-examined, and therefore the most interesting case of arsenic-eating, is one recorded by Dr Schäfer." Did Dr Schäfer see this case himself? Not a bit of it; his authority is a third person, a Dr Knappe of Oberzehring. Why did not Professor Roscoe address his inquiries to Dr Knappe? Well, this Dr Knappe saw a man, thirty years of age, in robust health, eat a piece of arsenious acid weighing 4½ grains, and on the next day another piece weighing 5½ grains. His urine was examined, and found to contain arsenic. He informed Dr Knappe that he was in the habit of consuming this quantity three or four times a week. Now, all this is very circumstantial; but it is not such evidence as would be admitted in a Court of Law. However, stranger statements are made by Dr Holler, who, together with friends named in his report, guarantee that they are acquainted with forty persons who eat arsenic; and Dr Forcher of Gratz gives a list of eleven persons in his neighbourhood who indulge in the poison. Now, what is the real value of these written statements? What *Government Officer* has yet *seen* a man eat 5 grains of arsenic? We are not even assured that Drs Holler and Forcher have actually *seen* these persons eat the arsenic. That the substance said to be consumed is really arsenic, Professor Roscoe tries to convince us by stating that he had received 6 grains of a white substance from Professor Gottlieb of Gratz, which, *he said*, had been given to him by an old woman, who *said* that she had seen a man eating it in the mountains. This was found, on analysis, to be genuine arsenious acid. So it might be; and yet the testimony is such that it would be laughed out of Court at the Old Bailey. Seeing is believing: the statements may be true, but we should like to judge for ourselves. We are forcibly reminded of the Greek braggart who boasted that he jumped forty feet when he was at Rhodes. "Very likely," responded one of the by-standers; "so fancy you are at Rhodes now, and jump it." In these days of gas, steam,

electricity, table-turning, and clairvoyance, we ought not to be astonished at wonders, however extraordinary; so we declare ourselves willing to believe, and will wait patiently for the demonstration.

THE MEDICAL STAFF IN CHINA.

The high sanitary condition of our Army in China reflects great credit not only on the departments at home, but also on the skill and management of Drs Mure and Rutherford, and the Medical Officers generally. Whilst the French General could not bring up more than half his troops, the other half having been disabled by sickness, the English General was in full force, his sick counting only by as many hundreds as the French General counted thousands. Our former Chinese war showed the reverse of all this. The importance, therefore, of good sanitary arrangements in the administration of armies was never more signally proved. It is satisfactory also to receive accounts of the gallantry and devotedness of the Medical Staff in attending the wounded before the Taku Forts. It is recorded that one shot passed between the legs of Dr Woodroffe and Dr Birnie, as they were standing together, —a sufficiently narrow escape to be remembered even by a veteran. It is also stated that the hospital tent in front of one of the forts on the south side of the river was fired into by the Chinese at the moment that Dr Rennie was in the act of amputating a leg. Many other interesting incidents of a similar kind are related. The excellence of the sanitary arrangements is, however, the chief matter on which we can congratulate the country.

THE EDITORSHIP OF THE 'ASSOCIATION JOURNAL.'

This enviable office has found candidates; the favoured among whom are, we understand, Dr Markham and Dr Thudichum, both clever gentlemen, and the latter is he who informed the Association, at their last annual meeting, that he was acquainted with the scientific literature of the whole world. He is obviously, therefore, the best qualified candidate, and no other gentleman can have a chance of competing successfully with a man of such universal pretensions. We hope he will obtain the appointment, in order that we may be provided with a grand exemplar of editorial capacity.

THOMAS SMETHURST.

The convict Smethurst, whose trial last year for the murder of Isabella Banks must be fresh in the memory of our readers, and whose subsequent conviction on the charge of bigamy caused him to be confined in Horsemonger-lane Gaol, will be liberated this month, his year of punishment being expired.

ALLOWANCES FOR WOUNDED OFFICERS.

Her Majesty has issued a series of new Regulations relative to pensions and allowances to be granted in future to wounded Officers of the Army. If an eye or a limb be lost in action, the Officer so suffering will be entitled to one year's full pay, and he will be recommended for a pension varying in amount according to rank. Minor injuries will be compensated also according to their severity. These are liberal regulations, and will, no doubt, be well received by the Army.

THE SPIRIT OF THE PERIODICALS.

(Continued from page 325.)

a few hours; and in three days afterwards, I saw the child laughing and playing on the sofa by the side of its new nurse."

We extract the following from the 'Journal of Practical Medicine and Surgery,' on *Fibrôma:*

"M. Huguier, who steadily continues his special studies on diseases of women, described to the Society of Surgery a new variety of tumour, which might be denominated interstitial fibrous growth (fibrôma) of the abdominal wall. Messrs Gosselin, Michon, and Chassaignac have observed analogous instances, and the total number of cases recorded amounts to nine. In all, the tumours presented much resemblance to each other. They are met with in young women, and occupy the vicinity of Poupart's ligament, inside the anterior superior spinous process of the ilium, to which they are often attached, as well as to the crista ilii, by a more or less elongated and firm pedicle. They are situated within the thickness of the abdominal walls, between the muscular layers in front, and the fascia transversalis and peritoneum, upon which they lie at the back, and to which they sometimes become adhesive. They seldom have any connection with the pelvic viscera, and do not interfere with their functions. They are more or less movable, and prominent either in the abdomen or above the skin. Usually indolent and very hard, they are spherical or ovoid, regular in their contour, and consist in a perfectly or partially developed fibrous tissue.

"In a case of this kind observed by Messrs Verneuil and Perret, these surgeons declined active interference. Messrs Huguier and Michon have been more enterprising, and the excision in their hands proved fully successful, although twice already the peritoneum has been opened. These growths should therefore be attacked at the first stage of their appearance, because, although the general health of the patients remains for a long time unchanged, these tumours invariably induce at last dangerous and even fatal symptoms."

The annexed article, giving an account of M. ARAN'S practice in *Typhoid Fever*, is also deserving of attention:

"M. Aran classes typhoid with eruptive fevers. When once they have set in, they progress through certain periods; but although their course may not be arrested, the Professor considers their symptoms may be modified and their duration abridged. With regard to treatment, typhoid fever presents very different indications according as the physician has to deal with the incipient or the more advanced stages. At the onset the system has not yet suffered, and active and persevering medications may be resorted to. A fact which now appears positively demonstrated, said M. Aran, is that the chances of success of the treatment are greater during the incipient stage than at a later date. M. Bouillaud, therefore, has recourse to his system of active and reiterated depletion during the first week only, because prostration does not make its appearance before the second.

"In this embarrassing question of the treatment of typhoid fever, M. Aran differs much from generally-received opinions. After much reflection, he has finally adopted M. Bouillaud's method. This medication, modified and adapted to the peculiarities of each case, has yielded in his hands remarkably satisfactory results; but he does not thence conclude that it is capable of suddenly checking the disease. When the heat of the skin is excessive, the tongue dry, thirst intense—when delirium is present, the brain wandering at night, and the abdomen very tender on pressure, unexpected amelioration follows repeated blood-letting. With regard to the propriety of applying the method in its utmost degree of energy, and of having recourse to local blood-letting in the left flank, M. Aran proceeds as follows:

"On both the first and second days, M. Bouillaud prescribes venesection morning and evening, and in the interval cupping with scarification. On the third day, this Professor takes blood once from the arm, and once by cupping; cupping only is resorted to on the fourth, a quantity of blood varying between four and six pounds being thus altogether abstracted from the patient. Now this rule is clearly not applicable to all cases. M. Aran, on the first day, usually prescribes phlebotomy, to the amount of 12 or 16 oz., and 15 leeches to the mastoids. This is repeated on the second day, and on the third the blood-letting is conditional. The leeches are preferably applied behind the ears, because M. Aran considers the morbid condition of the brain as more urgent than the abdominal symptoms.

"Even after this active depletion, the patients cannot be looked upon as absolutely cured; a certain amount of feverishness persists in the evening, together with borborygms and diarrhœa, and it is as yet impossible to allow solid nutriment. Beef-tea and soups are readily tolerated by the stomach, but solid food immediately recalls the fever, a circumstance due to the persistency of the local anatomical change and its regular progress, analagous to that of variola, scarlatina, &c. In subjects who have been treated by repeated depletion, convalescence sets in soon, and the disease is shortened by eight or ten days. But this should not constitute the only medication, and here M. Aran differs from Professor Bouillaud. When the bowels are constipated, he prescribes aperients, and emetics for gastric derangement. Aperients, says he, are never injurious, but they cannot work the miracles which many ascribe to them. When the disease is complicated by bronchitis, M. Aran finds a daily emetic beneficial, and also resorts to dry cupping of the chest, a remedy which M. Béhier earnestly recommends.

"As to nutriment, M. Aran is partial to the administration of food in many maladies. Recently he prescribed mutton-chops in a case of diphtheritic angina; he follows the same line of conduct in colica pictonum. In typhoid fever he does not hesitate to give nutriment at an early period, the stomach and upper part of the alimentary duct being entirely free from morbid change in this affection; but he does not recommend ham, like certain fanatical practitioners, nor farinaceous diet, which leaves a residue likely to keep up diarrhœa. He merely allows beef-tea, soups, wine-and-water, according to the condition of the patients and the effect of the prescription."

Dr NELSON has contributed an article on *Lingering Labour* to the 'British American Journal.' After condemning the impropriety of rupturing the membranes too early, he observes:

"However, this is not always the case, and often the very persistence and integrity of the membranous bag after, and even before, the completion of the first stage of labour, is in itself productive of vexatious delay, more particularly when the expulsive efforts are only of a moderate degree of severity, or even when they become, from, apparently, unappreciable causes, totally suspended. I have for the last eighteen years enjoyed something of a large private and consultation midwifery practice, and have adopted the following course, which, although it may not be entirely orthodox, has, however, the merit of being based upon a somewhat extended experience, and attended with invariable success. I am particularly careful to preserve the amniotic fluid till the os uteri is well dilated; and though the head is just being engaged in the superior strait, it often happens that the pains, although they may be strong, and probably as pressing as at any other period, still there appears to be a want of their direct application upon the fœtal body, the consequence is that the labour begins to flag, and at times is almost stationary; but if the

membranes are ruptured at this stage, the presentation being correct, and the waters evacuated, the uterus has *room* to contract, there *now* being a vacuum; it embraces more closely, or even moulds itself over, the various parts of the child still retained in the womb, and, necessarily, a speedy termination of the labour occurs, which would otherwise have been more or less prolonged. We sometimes observe that the abdomen, *cæteris paribus*, is in some women very large, giving rise to the idea that the womb contains two children, or that it is inordinately distended by the amniotic secretion: to determine the first point, a careful external examination will generally detect a sufficiency of the hard parts of one or two children; while the second may be defined by the uniformity of the abdominal surface and its unusual degree of fluctuation, combined with the distant feel of the fœtal parts. In such a case as this the labour cannot progress, as the over-distension of the womb tends to induce a paralysed state of its muscular fibres, and nature here teaches us the remedy, by a spontaneous and early discharge of the fluid contents of the uterus.

"Whether I have been more fortunate than other practitioners in having but lucky cases falling to my lot, I cannot say; but, of this I am certain, that I have never been more than from two to six hours in attendance on any case, even although called at the commencement of the first stage, and when the os was opened sufficient only to allow the introduction of the point of the finger, to satisfy myself as to the nature of the presentation. It may be proper, however, to remark that much of my success and the immunity of my patients from prolonged suffering may be possibly due to the use of my friend, 'Dr Pollard's Obstetrical Supporter,' an invention admirably calculated to afford every assistance to the parturient woman to lay out her strength as the calls of the uterine action demand; while to the physician it is a saving of an almost incredible amount of the being squeezed-and-pulled-around fashion, to say nothing of direct hard work."

We also quote the following remarks on the general and local remedies and other measures employed in the case under consideration:

"I conceive it will require but a few words in reference to the administration of opium in one form or other, tartarised antimony, and secale cornutum, or the use of bleeding or the warm bath: what are the indications for the use of the foregoing means?—The answer is comprised in a very few words,—first, to produce such a degree of general debility or languor as will facilitate the dilatation, or overcome the resistance offered by a preternaturally rigid os uteri; and, secondly, to increase the expulsive action of the uterus when this latter appears to fall into a state of atony. I will now, in a few words, point out under what circumstances the above various agents should be employed:

"1. *Opium.*—This drug, by relieving muscular spasm generally, and suspending uterine action locally, will, therefore, subdue the very distressing, and if I may be allowed the expression, the useless pains, by inducing a certain amount of sleep, and necessarily a corresponding immunity of suffering: on awakening, the patient will not only find herself refreshed, but the pains will be changed in character, increased in frequency and severity, and with them a greater aptitude on the part of the woman to render that assistance which is required of her; it is no use to administer this drug to suspend the prolonged pains caused by malposition, nor has it any *direct* power to relax a rigid os.

"2. *Tartarised Antimony; Bleeding and the Warm Bath.*—These means are only applicable in producing a sufficient degree of constitutional relaxation, as will tell upon a rigid and unyielding state of the os uteri; in the above case their use was most positively counterindicated; here was a soft and largely-dilated os, ready to allow of the passage of the product it had safely enclosed for a period of nine months, but in this it was foiled, owing to that assistance, which was so plainly pointed out, and was not rendered by those who should have done so.

"3. *Secale Cornutum.*—The last thing done was the administration of the secale; the pains, for two days, had been of the hardest and best adapted character; but, forsooth, they must be increased and multiplied to expel (!) the child, if that could be done, to the imminent risk of rupture of the uterus! Let my readers make a note of this mode of treating a case of midwifery; and, although I would not advise them to follow this *wise* course of practice, I would still have them bear in remembrance the not unexpected results.

"*Vesico-vaginal Fistula.*—During my first examination, which was necessarily more protracted than under ordinary circumstances, the strong odour of urine pervading the bed, and the peculiar acrid feel of the soft parts, together with the story of the *second* bag of membranes, led me to make a careful exploration of the superior and anterior walls of the vagina; there was no tumour, but, with a little manipulation, the index finger of the right hand entered a small opening back of the symphysis, and imparted the sensation as if in a close cavity, its edges were hard, thick, and resisting; there was no giving way of the parts around the opening, as is always the case by the gradual tearing of the amniotic membrane. The os uteri was fully dilated, and its superior segment not only very much thinned and relaxed, but allowed the free passage of the finger between it and the child's head. After the expulsion of the placenta, I had the opportunity of making a still closer examination, and became immediately satisfied that there existed an opening—a little less in size than a quarter-dollar piece—at the inferior and anterior portion of the bladder, just posterior to its neck; and this had been caused by the boring and scratching of a thirty-years' *helping* and experienced finger!

"To remedy, at once, the very sad results which would have resulted from the protracted neglect of this lamentable accident, and save the patient's life from being embittered by a repulsive infirmity, I advised the husband to keep a large-sized catheter in the urethra and bladder, that as much of the urine as possible might pass through the instrument; to syringe out, twice a day, the vagina with tepid and emollient injections; and after cleansing the wound of the lochial discharge, to apply the solid nitrate of silver, through a fenestred speculum, freely to the edges of the fistulous opening, once in two or three days. This plan was pursued till the cessation of the lochiæ, which took place about the twelfth day, when the tepid and emollient injections were changed to cool and strong astringent ones; the use of the catheter was still continued, and a piece of sponge introduced in the vagina, directly under the opening, to catch and retain what urine might drop through; the sponge to be renewed several times daily, thus ensuring comfort to the patient, and in a great degree, immunity of the soft parts from the contact of the acrid secretion. The opening gradually closed, till at the expiration of a couple of months it was reduced to the size of a probe; and this being cauterized, once or twice a week, with a sharp piece of the nitrate of silver, resulted in as happy and perfect a cure as it was certainly unexpected. Some eighteen months since, and nearly the same period of time, after the unfortunate occurrence I have just reported, the patient, now a resident of Vermont, has been safely confined of a living child, after a favourable accouchement.

"*Vesico-urethro-vaginal Fistula.*—The following case, which came under my care shortly after my return to Montreal, will not, I believe, be found an inappropriate conclusion to this paper. In March, 1859, I was requested to visit Mrs —, a native of Brighton, England, but for four years a resident of this city. I found her to be a woman of a fine *physique*, aged forty-six, the mother of several children; her last confinement having taken place ten years before, and although the labour presented nothing unusual, still, for some unexplained reason, it was concluded with the forceps. For some weeks after nothing particular occurred, though she complained of a more or less constant sense of weight and distress in the vagina, accompanied by a very frequent desire to micturate, which desire, however, was only relieved in part, and this not without some pain. Six months after her confinement she became aware of the presence of a small swelling in the upper wall of the vagina, back of the external opening of the meatus urinarius; the swelling gradually increased, till it filled almost completely the vaginal passage, preventing sexual congress, and attended with a throbbing sensation and increased weight and distress. One day, coming down a flight of stairs, she made a misstep, and in the effort to recover herself, gave a jump of a couple of steps, falling rather heavily; she immediately felt something give way, and found her person wet; on examination it was discovered that the tumour had been broken, and its contents had flowed upon her person and underclothing—there was nothing unpleasant in the odour of the discharge, save that it possessed a very strong urinary smell, was of a deep yellow colour, ropy, and of some consistence. This little fortuitous accident did not prevent her from attending to her household duties; on the contrary, it had done what several professional men, who had been consulted, could not do; it proved a certain temporary relief, and taught her that the same thing could be done, in after years, to secure a few weeks' or months' respite from her unpleasant ailment. Nothing unusual was observed after this occurrence, only that she now noticed that there was an increased and rather annoying degree of moisture about the external parts, and occasionally a few yellow spots upon her linen; to this she paid little or no attention, being under the impression that, like many other women, she was labouring under a slight attack of leucorrhœa. However, in the course of three or four months, this trifling discharge gradually decreased, at the same time that the small swelling commenced to show itself in the same situation it had occupied in the first instance; it passed through the same stages, till, having attained nearly the size of an egg, it was spontaneously ruptured, the contents evacuated, and relief followed as at its first appearance. Such was the state of things, and so it continued for ten years, recurring from two to three times a year.

"After her removal to this city, she was successively under the charge of three practitioners, who, however, did not appear to benefit her, although they never employed any local means—either by examinations or direct applications—they became satisfied that there was something wrong with the womb, but that time and the final change of life would, probably, effect the cure. Having heard the same story so often, it did not quiet her mind, and she had almost given up in despair, when she was recommended to call on me by an American lady.

"Having been made acquainted with the foregoing particulars, I proposed a vaginal examination, to which, at first, she rather objected, inasmuch as this mode of determining the nature of her complaint had never been hinted at by any of her former attendants; however, being a person of good common sense and proper feeling, when made aware of the necessity of this examination, she readily complied with the demand. At this time, a little over two months had elapsed since the emptying of the sac by the customary spontaneous rupture of its membrane, and it had now acquired near two-thirds the size of a hen's egg; it was situated half an inch posteriorly to the meatus urinarius, running backwards along the course of the urethra an extent of near two inches; it was firm and elastic, evidently fluctuating, and insensible unless subjected to undue pressure. A catheter passed readily into the bladder, and a small quantity of urine discharged. The first step in the treatment was to open the abscess—or sac—and then to endeavour to prevent its return by causing the obliteration of its cavity. With a lancet a small puncture was made in the most depending and anterior portion of the sac, when near two ounces of the same thick, yellow-coloured fluid were evacuated; a probe was now introduced in the opening, and the cavity carefully explored in all its directions, when a small passage or sinus—just admitting the probe—was discovered running parallel to the urethral canal, a distance of some two inches; a catheter was passed into the bladder, when catheter and probe both came into contact in the cavity of this organ. The peculiar features of the case were now very clearly explained and demonstrated—it was nothing more than an interstitial fistular separation of the urethro-vaginal mucous membranes, extending from the neck of the bladder to nearly the entire extent of the urinary passage. The manner in which the swelling was developed is to be explained as follows: A few drops of urine were constantly lodged in the sinus, which kept gradually increasing after the healing of the opening resulting from the spontaneous rupture of the sac, till it had acquired its ordinary size; then another break would take place, and immediately after this occurrence, for some days, and

even weeks, there was a continual oozing of urine through the *now* complete fistule, and which occasioned the disagreeable and unusual moisture of the parts; then the opening would gradually close, and proportionally the sac would increase by the greater amount of urine retained in it, and, although it would materially diminish during the recumbent posture, it was, nevertheless, never completely empty, by the retention of the thickened urine, the more fluid parts being either removed through the process of absorption, or flowing back into the bladder.

"The indication here was to lay open the track of the sinus, and attempt the radical cure by attacking the small vesical opening. This was done in the following manner: A grooved probe was introduced the entire length of the fistulous canal, and then a very small straight pointed bistoury was carried along, dividing the sinus and making it one with the vaginal canal. After the bleeding—which was somewhat profuse from so slight a division of parts—had been checked, a silver catheter was passed into the urethra, while a large-sized fenestered speculum was introduced into the vagina. I now found out the very simple cause of this poor woman's sufferings for ten years, a small *hole*—for it was nothing more nor less—at the junction of the body with the neck of the bladder; this was freely cauterised with a sharpened stick of nitrate of silver, and on withdrawing the speculum the caustic was slightly applied along the fistulous track, to promote the granulating process; a large bougie was introduced into the urethra in place of the ordinary silver catheter, and a piece of compressed sponge, in the vagina, directly under the vesical opening. This completed the first dressing, and I may almost say the only one, as a slight modification of the same process was gone through twice only at one week's interval, when the fistulous opening became perfectly closed; and, although I have since then repeatedly seen the patient, having been retained as the family physician, she has never, in fourteen months, felt anything like a return of her old complaint. Two months after the last application of the caustic, I made a most careful digital and visual examination, but could detect nothing to warrant me in saying that she was not radically cured.

"A third case, it should have been second in order of priority, in the person of Mrs ——, of Plattsburgh, presented itself to me a short time before I left that village, and pretty much under the same circumstances as in the last-named patient:—the general and local symptoms were nearly identical, so was the treatment, and the result equally successful and satisfactory; consequently, it is only neccessary to mention that for these cures, through a very simple and commonplace mode of treatment, an undue amount of credit has been awarded to me, when really it was only because I looked carefully into small things, and sought for the fountain-head of the mischief, being fully satisfied that if I took care of the cents, the dollars would take care of themselves. This axiom proved theoretically and practically true in both of my cases."

REVIEWS.

The Principles and Practice of Surgery. By William Pirrie, F.R.S.E. 2nd Edition.

This is a much improved edition upon the former one, and as a scientific work is creditable to the Aberdeen school. The opening chapter on Inflammation has been re-written by Mr Pirrie's son, who has ably set forth his subject. He has made use of Dr Bennett's diagrams of the progress of inflammation, and generally adheres to his views; but he is a moderate advocate of antiphlogistic measures in the treatment of inflammatory affections. The histology of tubercle and cancer is also illustrated with woodcuts; and there is an abundance of good plates (some of which are taken rom the works of the highest authorities), on all the subjects treated of throughout the work.

On Gout: its History, its Causes, and its Cure. By William Gairdner, M.D. 4th Edition.

A work that has gone through four editions recommends itself. The present edition has the advantage of the notes of the German translator, Dr Braun, and is, to that extent, improved.

On the Medical History and Treatment of Diseases of the Teeth, &c. By Benjamin Ward Richardson, M.A., M.D.

Having been appointed one of the Lecturers to the College of Dentists, Dr Richardson delivered a Course of twelve Lectures to the members of that body on the Diseases of the Teeth, and he has collected those lectures for wider publication in the present volume. The Author considers the various causes of disorder of the teeth as arising from constitutional cachexia, the hæmorrhagic diathesis, neuralgia, hysteria, dyspepsia, rheumatism, gout, the diseases of infancy and childhood, malignant affections, metallic poisons, diet and modes of life, chloroform, &c., and he suggests the appropriate management in the several instances. It is a useful work for Surgeons as well as Dentists, to each of whom we strongly recommend its perusal.

Phthisis and the Stethoscope. By Richard Payne Cotton, M.D. 2nd Edition.

A small book upon an important subject, therefore most useful in relation to diagnosis. No student or young practitioner should be without it.

Glycerin and Cod-liver Oil; their History, Introduction, Therapeutic Value, &c. By W. Burnham Willmott.

Mr Willmott, being a chemist, enters elaborately into the various modes of preparing glycerin and obtaining cod-liver oil, which, however, we shall not reproduce.

We quote some of his remarks on the therapeutic uses of glycerin.

"After tracing the history of glycerin, and remarking upon its great value in cutaneous diseases, &c., M. Cap goes on to say:—'But I must hasten to my own personal remarks, which apply to the part which I consider glycerin ought to take in pharmacy. It is evident that its unctuous state, its slightly hygrometric properties, its analogies to water and oil, and finally its perfect harmlessness, render this substance fit for many various uses. It blends with wonderful ease with every form of medicament. It may be used either alone or with other therapeutic agents. It mixes in all proportions with water for baths, injections, fomentations, and lotions of all descriptions. Applied to burns or other wounds, it keeps them from the air, and maintains the suppleness of their edges. When added to cataplasms, it preserves their softness, and, which is very important, it prevents them from adhering by their edges to the surfaces on which they are applied. This combination of properties presents, as may be seen in glycerin, a new and valuable *excipient* to be added to the scanty list of bodies of this nature now at the disposal of art—an excipient which appears to hold a place between water and oil, for it participates in most of the qualities of both. Glycerin unites as well with aqueous and alcoholic liquids as it does with lard, ointments, pomades, and soaps. It will serve as a base for liniments, ointments, and embrocations; it will mix with extracts, tinctures, alcoholates, and medicinal wines; a few drops of glycerin, added to a pillular mass, will prevent it from drying, &c.; it will consequently assist in most uses of medicine, surgery, and veterinary science, adding to any preparation with which it is mixed the advantage of its lenitive, sedative properties, softening the tissues, and preparing them for the absorption of the medicinal substances to which it is united.

"But this is not the limit of its pharmaceutical uses. Glycerin dissolves the vegetable acids, the deliquescent salts, the sulphates of potassa, soda and copper, the nitrates of potassa and silver, the alkaline chlorides, potassa, soda, baryta, strontia, bromine, iodine, and even oxide of lead. It dissolves or suspends the vegetable alkaloids in the same manner as the aqueous liquids, and at the same time the resulting products may be used for the same purposes as though mixed with oil. Thus the salts of morphia dissolve in it completely, even cold, in all proportions. Sulphate of quinine, in the proportion of one-tenth, dissolves in it when hot; but when cold, separates in clots, which, when triturated with the supernatant liquid, give it the consistence of a cerate, very useful for frictions and embrocations. It is the same with the salts of brucine, strychnine, veratrine, and most preparations of the same order, which enables us to consider that we have now, if not medicinal oils with a vegetable alkaloid base, at least a series of new preparations which will fufil a perfectly analogous use in therapeutics."

The Author particularises the various affections of the ear, skin, and eye, in which medical practitioners have extolled its virtues. With reference to its use as an excipient in the place of lard, Mr Willmott very fairly admits its inferiority. In fact, this has long been proved. There is one use of glycerin that must not be overlooked—that of its combination with the iodide of iron, which it effectually preserves. So much has been written on the subject of cod-liver oil, and its therapeutic uses are so well understood, that we deem it needless to quote from our Author on this topic. His little book is a useful remembrancer.

Operative Surgery, adapted to the Living and Dead Subject. By C. F. Maunder.

We hardly know better how to exemplify the usefulness of a little treatise of this nature than by extracting a portion of it. We will therefore take the following paragraphs on a very common disease—*Nævus.*

"Treatment by *ligature* as already described under article 'Ligature.'

"By *pressure:* a mode only to be adopted when the aneurism by anastomosis lies over bone.

"By *injection* of some irritant fluid, as tincture of iodine, or a solution of perchloride of iron: a puncture sufficiently large to admit the nozzle of a small syringe is made in the skin, and a quantity of the fluid, from five to fifteen drops, in proportion to the size of the tumour, is injected after *subcutaneous incision* has been adopted. Inflammation, followed either by obliteration and absorption, or by suppuration and cicatrization, is the result.

"By *seton:* one or more threads may be passed through the tumour.

"By *vaccination:* applicable to very small examples of this disease.

"By *subcutaneous incision:* the blade of a knife, or cutting needle, being passed in various directions, so as to break up or cut up the enlarged vessels.

"By *actual cautery:* one or more wires being passed through the tumour, and heated by electricity.

"By *ligature* of one or more arteries, or even a main artery: applicable to those cases in which arteries enter largely into the formation of the tumour, and perhaps previous to the free use of needles at various points, or under circumstances consequent on position, where the tumour cannot be treated locally.

"By *caustics:* one of these agents being applied to the surface, or introduced into the interior, on a probe or needle.

"By *excision:* the surgeon must cut wide of the tumour, otherwise bleeding may be profuse.

"When this plan can be adopted, it should be had recourse to, because, when the wound heals, a linear cicatrix is the result; but often, by other means which destroy much skin, an ugly scar is produced, and increases in size as the patient, if a child, arrives at manhood.

"In all cases the surgeon should destroy as little skin as possible, to avoid ugly scars and deformities."

All the operations applicable to arteries, the excision of bones, and minor surgery generally, are thus tersely and lucidly explained; and more we scarcely say in favour of this little *brochure.*

We must add that the work is well supplied with good illustrations.

Aspirations from the Inner and Spiritual Life, aiming to reconcile Religion, Literature, Science, Art, with Faith, and Hope, and

Love, and Immortality. By Henry M'Cormac, M.D.

That Dr M'Cormac exhibits a thoughtful, tender, yet eccentric genius in this volume, every reader of it must allow; at the same time the review of the book would be beyond the province of a Medical journal.

A New and Rational Explanation of the Diseases peculiar to Infants and Children, &c. By Thomas Ballard, M.R.C.S.

Mr Ballard's leading notion is, that fruitless sucking is the cause of most of the diseases of the infantile state; and though we cannot go with Mr Ballard the full length of his views, we are satisfied, nevertheless, that there is much truth in them—truth not yet recognised. He says:

"Perhaps the most common and familiar instance of fruitless sucking, causing frequent evacuations from the bowels in the young of the human species, is that which occurs during the first few days of extra-uterine life: every accoucheur and nurse knows, that for the first few days in all cases, and for a longer period in many, the infant's bowels are moved several times during the day, and the evacuations are commonly green. This effect is attributed to a supposed purgative property possessed by the colostrum, or first milk, that is secreted—a view not merely based on popular opinion, but sanctioned by some of the highest obstetrical authorities. I have made many experiments in reference to this subject, and have quite satisfied myself that this theory is unfounded, and that the frequent stools of newly-born infants depend upon their sucking at the breast before the milk is secreted in sufficient quantity to satisfy their craving. If the breast of a woman recently delivered be examined by means of an exhausted glass, it will be found that no milk can be obtained until the third day, and very little until after then; yet both the nurse and mother will be under the impression that the infant obtains plenty when it sucks.

"*Case* 3.—A patient was delivered of her third child early on Thursday morning; the nurse persisted that the child obtained plenty of milk in the evening of that day; the evidence being—that she heard it swallow. I could not obtain sufficient for a microscopical examination until Sunday, and the secretion was not freely established until Monday.

"I have repeated this examination, and have never met with a less favourable result: frequently, especially in first confinements, a much longer time has elapsed before the breast yielded milk, but in no cases have I found it earlier, and I quote the above case because the woman has always been a good nurse; she is of mature age, and in every respect healthy, therefore a good average illustration of what usually occurs. I have prevented infants from sucking until I could obtain milk by means of the exhausted glass, and then carefully watched their evacuations, and in no case has there been any evidence of a purgative effect."

Again:

"This sympathetic relation, then, displays itself in young infants most frequently by the occurrence of erythema in connection with green-stool diarrhœa, caused by fruitless sucking, which symptoms, with the addition of the peculiar affection of the mouth, constitute a disease almost *peculiar* to sucking infants, the exact nature of which I believe has not before been clearly demonstrated: I allude to thrush or muguet. . . .

"The true nature of the disease I suppose to be, that the delicate mucous membrane of the month becomes inflamed, in consequence of excessive sucking, and that an inflammatory exudation results, which, from its situation, being warm and moist, affords a very appropriate nidus for the growth of the oidium which is found so universally growing under circumstances equally favourable to its nature; the accompanying enteric symptoms coinciding with those I have previously described as resulting from fruitless sucking. The best confirmation I can adduce in proof of the correctness of this opinion, is the fact that in all instances where I have been able to make my views of the cause of the disease understood, no case of thrush has occurred; and in addition to this, the relation of some cases of which I have notes, where I have successfully treated the disease in accordance with them."

The Author points out a great defect in the ordinary teats used for artificial sucking, viz. that of collapsing when the child sucks—a defect we have also noticed, and when an artificial teat has been applied to a flat broad nipple to shield it, we have seen an infant literally starved. We cannot transcribe the entire list of ailments, both infantile and maternal, which Mr Ballard attributes to this cause; for, having laid down his foundation, he builds upon it a considerable superstructure. We agree with him, however, that excoriated nipple and mammary abscess are due to this cause, with this qualification, however, that ineffectual sucking rarely occurs unless the nipple be imperfectly developed—a circumstance by no means infrequent among modern mothers—or the skin exceedingly delicate. Mr Ballard's book will repay perusal.

Letts's Appointment Diary

Is one of the best we have seen. It provides space for the registering of appointments for every hour in every day of the year. Its compass is so small, moreover, that it can be carried conveniently in the breast-pocket.

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.

October 21st.—Removal of Sequestrum, and Necrosed and Carious Bone, extending the whole Shaft of Tibia—Removal of Lower Jaw—Tumour on Thigh.—Mr Bowman.

October 28th.—Lithotomy.—Mr Fergusson.

Removal of Sequestrum, etc.

This patient, about eight years of age, a Welsh boy, could not speak a word of English. Had been suffering from long-continued scrofulous disease in the whole shaft of the tibia. Sinuses existed along the length of its anterior aspect, from above to below. Sequestrum stuck out for about two inches at the superior sinus, and from thence (and portions also above) lay embedded along the whole shaft. Mr Bowman proposed, as the best treatment, to separate it by detached pieces, thus avoiding a large suppurating wound. Such large wounds with superficial hard solid bone upon their edges caused great irritation and suffering. They were also most difficult to heal, which occurring with great suppuration in an attenuated, worn-out subject like this patient, was particularly to be avoided. Mr Bowman first dilated freely the lower sinus—gouged out a large cavity at the extremity of the tibia. In this part, amongst the cancellous structure, a large quantity of pus had formed, which escaped. He then removed the projecting piece of bone at the upper sinus. With nippers he removed more necrosed bone, and enlarged the wound. Cold dressings were applied.

Removal of Lower Jaw.

The patient was a young man about twenty-two years of age. About ten years since he had swelling of the gum, near the last molar tooth. This having increased, was burnt away with acids while in the country. He remained well until about twelve months ago, when it rapidly increased. It became imbedded in the alveolar process and jaw-bone, which became flattened and expanded by its continual pressure. It thus buried itself in the bone, which became greatly thickened and enlarged. Mr Bowman, after sawing through the bone near to its symphysis, dissected away the half of the bone, and removed the ramus of the jaw at its condyloid extremity. Cold dressings applied.

Removal of Tumour on Thigh.

This patient, a female, had a large tumour on the anterior aspect of the right thigh. It had been ten months growing. Mr Bowman thought it had had a longer growth. He saw it last August for the first time. It was very obscure in its character, and lay very deep amongst muscles and large vessels—as malignant tumours do frequently. He diagnosed it to be of fibro-cystic growth. It caused great pain. Nothing could be decided until an exploratory operation was made. A longitudinal incision about six inches long was made, and tumour removed. It was now examined.

Lithotomy.

Mr Fergusson gave the history of this case. He said—This is a young man, come from the country, wishing for rapid easement and relief from this disease, having suffered for eighteen months or two years. The question in the case was, lithotomy or lithotrity? I told him his was a fit case for lithotrity, which required a long and patient proceeding. He preferred the operation of lithotomy. I readily diagnosed a moderate-sized stone, either mulberry or lithic acid constituents. The sound, he said (holding the stone to view), touches these little eminences distinctly in the bladder and tells this. The operation which followed was a display of art unrivalled in precision, promptness, and celerity. Surgery is an art, as also is it a science. It permits description, and gives æsthetical results. A small leather bag turned out four or five instruments—a bone syringe, three forceps, a sound, and a staff. The patient has been sounded on the operating table by Mr Wood. Mr Fergusson seats himself opposite the patient, and takes from his pocket a clasp knife. He is heard to say, "A little nearer the margin of the table." The clasp knife by this time has passed by a second cut into the staff at the membranous part of the urethra. It only notches the margin of the mucous membrane of the prostate, when it is returned in its line of advance with a lateral sweep outwards. The index finger of the operator's left hand being advanced in the line of retreat of the blade of the knife, the forceps are passed by guidance of this finger, the palmar aspect of which reaches and lies upon the stone in the bladder. The finger returned, a slight gnsh occurs which the forceps instantly stops. The forceps held with firm and precise grasp, the blades being partially opened, are jerked with a semi-rotary jerk, by which they clutch the stone, and another semi-rotary movement brings the blades containing the stone to view. The whole operation was done in thirty seconds. The syringe throws up into the rectum one-third of a grain of morphia, and the patient is in his bed again in a quarter of an hour after leaving it. However much we may have failed to describe this operation, we have a much more difficult task to record—the simple yet graphic commentary of the operator. Mr Fergusson said, in his *naif* and practical manner, there was nothing to be noticed particularly in this operation. "I performed the lateral operation, I believe, as Cheselden did it, in the usual way. The usual way is a figure of speech, with but little meaning. I know a very eminent surgeon who performed this operation in his usual way. On being asked, he forthwith described how he held the knife. It proved, nevertheless, that he held it the contrary way. So that the usual way has much latitude in practice." He further stated that this was the first adult patient in whose case he had omitted to fasten hands and feet together during the operation. Under chloroform, this was not required. By abandoning this practice, Mr Fergusson said, we got rid of a cruel and objectionable feature of the operation. In the case of the vigorous young man he had just operated upon, he the more readily relinquished it, seeing around him stalwart young men ready to give aid if necessary. Children can be held without this barbarous treatment; strong youths, perhaps, require to be so fastened. He then gave a lucid *rationale* of the operation he had performed. He remarked that the size of the forceps must be judged by the operator; that the finger, on introduction, dilates the prostate, and also the tissues. The tissues in some subjects are much more easily dilated than in others; and while the bladder is distended, the stone is readily seized. To surely effect this part of the operation, the beak of the forceps must be cautiously guided into the margin of the prostate, or it may pass into the subcellular tissue, and not reach the bladder. When so dilated, and the bladder is distended, you seize the stone easily, aided by the finger, and the sudden jerk described above brings it into the grip of the forceps. If the water escapes, you then adopt another mode: you use the forceps as a sound, and seize the stone on its flattened aspect; whereas you seize it on its wide *axis* if the bladder be distended. The morphia is introduced *per anum*, to allay irritation. The knife used on this occasion is a

study. It is about six inches in length, three-quarters of an inch at its point, having a cutting and rather boldly convex edge, sweeping gradually until at its distal end it becomes slightly concave to the handle, which is solid and substantial. This is a powerful instrument for the size. Mr Fergusson said, the finger should be made familiar with the notch made in the margin of the prostate; he added, "I am so familiar with this margin of the mucous membrane of the prostate, that it is my sure guide in the operation."

Resection of Knee-joint.

A very interesting case of this operation was introduced to the theatre. The young man had been operated upon seven years since. It was a perfectly-developed and strong limb; but for the scar no difference could be discovered. Mr Fergusson related, that a surgeon was shown the skeleton of a leg upon which resection had been performed, and could not be convinced of the fact, but insisted it was in its normal condition.

Dislocation of Cervical Vertebræ, and Fracture of Humerus.—Mr Erichsen.

Edmund Day, a butler, fell from a cab while drunk, and was admitted to University College Hospital on the 2nd of October, under the treatment of Mr Erichsen, in a helpless state. The stomach-pump was used, and he rallied, and could speak, but with difficulty. When examined, a comminuted fracture of the left elbow was diagnosed.

Oct. 3rd.—Patient passed a bad night; complained of inability to move in bed, and great pain in cervical region; was unable to sit up in bed, and when supported suffered much pain. The neck was found much swollen and tender, giving great pain when bent. Both lower extremities were paralysed, with partial anæsthesia of both; the arms were out of control by voluntary motion, but he could close the hands; the vertebræ of neck had an inclination to the left side. No water has passed since admission, therefore it was drawn off by catheter; during the day constant priapism sets in; the body is much warmer than normal.

Oct. 4th.—Priapism still continues; pain and stiffness of neck the same as yesterday; patient takes his food tolerably well; urine removed night and morning; bowels relieved by injection.

5th.—Patient complains of great tightness, as if of a cord across upper part of abdomen, but the abdominal parietes are quite relaxed; sensation in lower limb somewhat improved; paralysis same as before; urine drawn off as before; sphincters not relaxed; heat of surface normal; passes wind freely; complains of back being tender, and is placed on spring bed.

6th.—Much the same as yesterday; not so much tightness, however. Priapism constant.

7th.—Priapism less constant; has seminal emission; motions pass involuntarily; urine highly ammoniacal.

9th.—House-Surgeon called up during night to draw off urine, which has the smell of sulphuretted hydrogen; the other symptoms persist.

10th.—Complains of much tightness and pain in region of stomach, and of his hands and arms feeling cold and numb; his hands involuntarily close when opened: after enema his bowels operate involuntarily.

11th.—Had a little sleep during night, and feels better; yesterday he wandered in his mind at times; seminal emissions take place two or three times during twenty-four hours without the patient's knowledge; is less irritable than yesterday, and pain in arm less intense: urine, which is highly offensive, has to be drawn off three or four times during the day.

12th.—Had a very bad night, wandering at times; urine drawn off during the night; left hand of a pallid white colour, perfectly cold, but when examined at later period was found burning hot; right hand tense and swollen, and marked with erysipelatous blush; abdomen tympanitic; flatus passes involuntarily, and in abundance; bowels acted semi-involuntarily, the patient being partially conscious that something was passing from him during the motion; tightness and feeling of fulness about chest and abdomen much the same as before.

13th.—Tightness about chest and abdomen becomes paroxysmal, with feeling of suffocation, felt most intense before emptying the bladder, after which he felt relief. Complains of heavy aching pains in whole of left arm during these attacks, which are at intervals; the heat of the limb is more than normal; has slept during day, and altogether is more easy: towards evening had violent convulsive motions in right arm.

14th.—Bowels opened during night involuntarily; little sleep; cries out from constant pain; has difficulty in swallowing; takes little or no nourishment; breathing very irregular—as low as six respirations in a minute, or else gasping quickly. Tongue dry and brown; rhonchus on breathing since middle of night.

15th.—Expired at one a.m. An hour and a half before that event, his arms were so violently thrown about that they had forcibly to be restrained, during which time he was unconscious.

16th.—Forty-eight hours after death, a post-mortem gave the following: Skin ranging from fifth cervical to last dorsal vertebra, much discoloured. An incision was made along the line of the vertebræ, from the surface down to the neural arches; much blood was effused in the subcutaneous tissue, extending from the occiput to about half-way down *ligamentum nuchæ*. The muscles were not injected, but had a normal appearance; the veins were full of uncoagulable blood; the vertebræ were then removed from the axis to the seventh cervica vertebra. On examination, the fifth and sixth cervical vertebræ were found disunited by rupture of their ligaments. At the same time, there was found complete fracture across the right peduncle of the transverse process of the fifth cervical vertebra, allowing the process with the vertebral foramen to move freely irrespective of the body of the vertebra. On removing the neural arches with the spinous processes of the vertebræ, a great quantity of extravasated blood was visible over the whole length of the external surface of the dura mater: also, here and there, large clots of blood, particularly opposite the third and fourth, and fifth and sixth cervical vertebræ; more at the side and in front of the cord than at the posterior aspect. On cutting into the dura mater, and reflecting it on either side, vessels over the pia mater were seen gorged with blood, with patches, at intervals, of ecchymosis; but no marked clots were visible.

WESTMINSTER HOSPITAL.

Hemiplegia of Left Side.

Robert Mason, ætat. twenty-five, admitted into King William Ward, Westminster Hospital, on October 11th, 1860, under the care of Dr Basham.—Enema terebinth.; empl. cantharid. nuchæ; haust. sennæ co., ℥jss.

12th.—Skin cool; perspiration profuse. Bowels relieved by enema; stools dark colour. Urine scanty, high-coloured. Pulse 80, of good strength. Sleeps badly. Tongue protruded naturally. Complains of loss of power on the left side of the body; no power in the left arm—sensation less than natural, no *reflex action*. The leg can be slightly extended and raised, but cannot be flexed. Light diet; beef-tea. Tries to whistle, but does so imperfectly; the mouth is drawn very slightly to the left side. Ol. crotonis tigli, ℥vj.; extr. colocynthid., gr. viij. Complains of difficulty in chewing food, which works out at corner of mouth. Speech difficult; twitching of mouth. Difficult micturition, with straining on passing urine.

History.—On Sunday morning, awoke with desire to stool; found himself unable to move left leg or arm; urine and fæces discharged involuntarily; mouth greatly drawn to the right side, and speech thickened. The day before, had giddiness with pain between the temples, which had existed for some time before. The mouth is become less drawn than on the day of attack. Bowels generally open daily; memory good; vision weak from the period of childhood. Has two children, quite healthy.

13th.—Blister acted well; bowels not open; urine scanty and thick; pulse 84, good.

14th.—Haust. sennæ co., ℥ij.

15th.—Much the same, but mastication better. Repet. pil. hora somn. Repet. haust. ℥jss. mane. Blister remains open, discharging freely. Bowels moderately open; urine free, less straining on micturition; pulse good, quiet; has more control over left leg, can draw it up tolerably well; arm remains powerless; no pain in head; whistles clearer and more powerfully.

17th.—Skin natural, and also the scalp; tongue flabby. Bowels open twice yesterday. Pulse 68, moderate strength. Movements improving greatly. Can get out and into bed with little exertion, which he was incapable of on admission. Can raise and extend the left leg to some degree; and can raise and swing the arm slightly. Whistles much more plainly; sleeps well; appetite improves, wants more to eat. Blistered surface discharges moderately. Repet. pil. hor. somn.; haust. sennæ, ℥jss. statim.

27th.—Continued improving since last report. Bowels open, but draught occasionally necessary. Pulse reducing gradually to 64; its strength greater. Mouth becoming natural, and whistles almost naturally. Has much more extensive motions of leg and arm; can move his fingers about, and squeeze a hand, which he could not do until now. Bowels freely open three times to-day. Face occasionally flushed, which is natural to him.

On November 9th, he was discharged relieved, the symptoms having favourably progressed from the last date, bowels continuing, with assistance of the pills, open every alternate day. Urine rather scanty, but not difficult to pass it. Pulse rising to 84, and stronger; and so on, until it became natural. Appetite good; sleeps well. Has less flushing; aspect pale. Perspires freely at night. Complained of pain in the right knee, and likewise in left shoulder when the arm is hanging; more power is gained over the left arm when it is raised by its own power without help, and with assistance can be normally extended, which it could not before. Power of left leg returned slowly.

We are indebted for the above notes to Mr Middleton, House-Physician.

CLINICAL REPORTS OF CASES

UNDER THE CARE OF MR BAKER BROWN, AT THE LONDON SURGICAL HOME.

(Reported by Arthur B. Brown, Clinical Clerk.)

Polypus Recti.

Mrs R., æt. fifty-nine, mother of three children. Catamenia ceased three years ago, after an attack of variola; ever since which she has been suffering from supposed uterine affection, and gone through the usual treatment for fulness and enlargement of that organ. Her bowels have been seldom relieved except by medicine; she has been subject to piles, which sometimes bled: has also had great irritability of stomach, requiring spoon-diet for some time.

Examinatio per vaginam.—The uterus was found perfectly healthy, and in its normal position. On examining the anus, the sphincter was found to be so firmly constricted as to hardly admit the finger. Immediately within its orifice was found a bleeding pile. On passing the finger two inches up the rectum, a large polypus, the size of a French bean, was discovered, with a thin pedicle of about an inch long.

Treatment.—Jan. 26th, 1860.—The pedicle was tied with twine, and the polypus cut off. The internal pile was tied, and the constricted sphincter freely divided on each side of the anus. Oiled lint was then introduced within the rectum, and an opiate given.

March 21st.—Discharged perfectly cured.

Remarks.—Mr Brown observed to the Medical visitors, on the Thursday preceding her discharge, that this was a case of great interest in a practical point of view, the patient having laboured under a supposed affection of the uterus, and having become emaciated from the constant irritability of the stomach. The rectum had never been examined, and, consequently, the polypus, which was the real exciting cause of her illness, had never been discovered. The marked improvement in her general health, and the increase of flesh consequent thereon, was most marked before she left the institution.

Fissure of the Rectum—Supposed Disease of the Uterus.

A. M. O., ætat. forty-two, admitted June 12th, 1860. Has been married twenty-six years, and has had eleven children and ten miscarriages. The last child was born two years ago: ever since she has been ill; has suffered much from heat, pain, and bearing down of womb. For the last six or seven months has been obliged to take large doses of medicine before her bowels would act; and when they did so, the motions gave great pain. She has been treated for inflammation of the womb, but has never had the rectum examined.

Examination.—The womb was found quite healthy; in the rectum were two fissures, into each of which dropped a small polypoid body.

June 21st.—Mr Baker Brown removed the

polypoid bodies, divided the fissures, and plugged the rectum with oiled lint.

23rd.—Oiled lint removed, and simple oil applied by the finger to the cut surfaces.

24th.—A dose of castor-oil relieved the bowels, which acted with far more ease than for a long time previously. She was ordered to take a dose of castor-oil every other morning, which was always followed by a comfortable evacuation without any pain.

July 11th.—Parts nearly healed; caustic applied to a small piece of excessive granulation.

28th.—Discharged perfectly cured.

Remarks.—This was another case where the disease was attributed to the uterus, but where, as has been shown, the real cause of her suffering arose from the rectum.

(To be continued.)

OUR NOTE BOOK.

MENORRHAGIA TREATED WITH CREAM OF TARTAR.

About twelve years ago, a writer in some of the European journals spoke in high terms of the bitartrate of potassa in the treatment of menorrhagia. This remedy in this affection has received but little attention at the hands of the Profession, and certainly has not secured professional confidence in its powers over this disease. In the 'St Joseph Journal of Medicine and Surgery' for July, Dr J. A. Chambers has an article upon the subject. He says he has used the remedy for the last twelve years, in this disease, with greater success than has followed any other remedy in menorrhagia. He directs his patients to "take three teaspoonfuls of the medicine and put it in a sufficient quantity of boiling water to dissolve it, adding sugar sufficient to make it palatable, to let it cool, and drink the quantity in twenty-four hours; when that is gone, to use more in the same way."—'American Medical Monthly.'

CONSTIPATION TREATED WITH COLCHICUM.

In the 'Journal of Materia Medica' for July, Dr Joseph Bates has an article upon colchicum. Among other affections in which he speaks well of it, he mentions constipation, in which, he says, it has seldom disappointed him. "For constipation, I give eight drops (of the tincture) every four hours, and continue its use a few days, adding or diminishing the dose as circumstances may indicate."—'American Medical Monthly.'

LUPUS.

In the 'Boston Medical and Surgical Journal' for July 5th, Dr J. C. White has an article upon lupus, which shows, on the part of the Author, a thorough acquaintance with the subject. Upon the treatment his remarks are full. We quote the most important and more novel: "But of all remedies for lupus, the anhydrous or stick nitrate of silver is incontestably the best, and the best in every case. It can be trusted in the hand of any one, however inexperienced in the treatment of the disease, and cannot possibly do harm, because it is held in complete control, and because the sound tissues are very little, if at all, affected by its contact, while the diseased parts may be thoroughly pierced and penetrated to their very bottom. It is not enough, however, as is often done, to apply it to the surface merely, but a sharply-pointed stick of the material, set firmly in a quill, must be taken, and thrust boldly down to the limits of its penetration. In the beginning of the treatment it is well to apply the caustic thus several times, at intervals of three or four days, till we obtain a smooth, even, suppurating surface. Arrived at this point, the process must be repeated twice a week, after which once will be sufficient. The scars which result from this treatment are the fairest and finest of scars."

Dr White does not claim this as an original plan with himself. It was perhaps first put in practice by Prof. Hebra, but he thinks it is too little known and practised.—'American Medical Monthly.'

COFFEE IN DELIRIUM TREMENS.

Before the Boston Society for Medical Improvement, as per report in the 'Boston Medical and Surgical Journal' for June 28, the subject of delirium tremens was up for discussion. In the expressed opinions of members present, there seemed to be a lack of confidence in the remedial influence of opium. "Dr Minot asked if any gentleman had tried strong coffee in the treatment of this disease? A former house-pupil at the Hospital, who had seen much of the disease, had great faith in its efficacy, as had also the nurse who took charge of the delirium tremens patients. It is given in the quantity of two quarts in twenty-four hours." . . . "Dr C. E. Ware had given strong coffee to a patient in the Hospital lately, with apparent good effects."—'American Medical Monthly.'

BISMUTH IN THE TREATMENT OF BURNS.

In the 'N. A. Medico-Chirurgical Review' for July, Prof. T. G. Richardson has an article on the treatment of burns and scalds with the subnitrate of bismuth. He says he has previously been in the habit of using the white-lead and linseed-oil, as first recommended by Prof. S. D. Gross. Though he considers this treatment with lead superior to all other applications previously recommended, he says, "I am now convinced by ample experience that the bismuth is better." . . . "I was induced to give it a trial from a consideration of its well-known effect in calming irritation, and even actual inflammation occurring in mucous membranes, the condition of these structures under such circumstances bearing a very close analogy to that of the skin after a burn of the first or second degree. When I first began its use, I combined it with linseed-oil in such proportions as to form a consistent paint, but subsequently substituted glycerine for the oil, and I am now inclined to think that the combination can never be surpassed, since by it every local indication is fully met. To prepare it, it is only necessary to rub the bismuth in a mortar with a sufficient amount of glycerine to form a paste or thick paint, which should be applied to the affected surface by means of a camel's-hair pencil, or a mop made of soft linen." . . . "In burns of the first degree, one such application will often suffice; but in those of the second degree, it may be necessary to repeat it, in part at last, from day to day, in consequence of its disturbance and the wetting of the cotton by the subjacent discharges."

We have neglected to mention that, after the application of the bismuth and glycerine, Prof. Richardson advises that the parts be covered "with a sheet of clean carded cotton, or a layer of cotton batting, which may be confined, if necessary, by a thin bandage lightly applied." He says, "The carded cotton or cotton batting I look upon as a most valuable adjuvant, and is superior to anything with which I am acquainted for warding off pressure."

Dr W. C. Nichols, House-Surgeon of the Charity Hospital, New Orleans, upon the recommendation of Dr Richardson, has put the bismuth and glycerine to the test of experience, and freely accords to it all the praise which Prof. Richardson bestows upon it."—'American Medical Monthly.'

THE OIL-WELLS OF PENNSYLVANIA.

The oil is found in Pennsylvania, Western Virginia, Ohio, New York, Canada, and other places. The wells yield, by pumping, from ten to twenty-five barrels per day of the crude oil. The yield of the refined article of the Pennsylvania oil is about 85 per cent. of the whole. One well gave ten barrels a day of pure oil, which was barrelled and sent to market as it came out of the ground. The owner was not satisfied, and deepened his well, and in eighteen hours 110 barrels were collected from it—but this proved to be very impure. The crude oil burns dimly, and is a very good lubricator, and when refined has less smoke and less odour than any other oil, and is not explosive, while its illuminating power is equal to the best coal oil. In Illinois the oils occur in a limestone, and the loss by distillation is about one half. These oils everywhere occur, for the most part, about one geological level. The oil seems to have distilled from the carbonaceous deposit below, and it may be the product of animal as well as vegetable remains. Professor Pugh states that the petrolcum is used with great success by the students in the institution to which he belongs, and they find it to burn better and to be generally superior to the common oil. Professor Whitney thinks it likely that these oils are of animal origin, as no vegetable had been discovered in the Hudson river formation from which also oils have been obtained.—'Chem. News.'

LINEAR CRUSHING, AND ITS APPLICATION TO THE TREATMENT OF HÆMORRHOIDS.

The interesting wards of M. Chassaignac present a peculiar attraction to the numerous practitioners who visit them, with a desire of becoming initiated into the operative methods and procedures to which the name of the Professor will remain attached; and to those who, like ourselves, have long been convinced of the advantages derivable from linear crushing and the drainage of abscesses, it is equally interesting to watch these surgical innovations in their progress, and to witness the modifications which must naturally flow from daily experience.

At his weekly conference of September 24th, M. Chassaignac produced four patients whom he operated on with the *écraseur*.

The first bore an enormous lipoma upon the right shoulder. A portion of skin was removed with the *écraseur* from the lower part of the tumour, and through this aperture, which might, in its widest diameter, measure four inches, the surgeon endeavoured to press out the lipomatous growth. By using a certain amount of violence, the operator would assuredly have succeeded in his object; but being more anxious for a safe than for a brilliant performance, he proceeded with much caution. He stated that experience teaches that if, after dividing the skin, enucleation is accomplished with too much force, the imprudent manipulation of the tumour imperils the ultimate advantageous results of the procedure. The mass should be carefully detached with the fingers, slowly drawn out, and divided into fragments with the chain-saw; its attachments to neighbouring structures must be severed in a like manner; the knife and scissors may, if necessary, be resorted to, but the chain-saw is preferable, as it prevents subsequent hæmorrhage, the fatal consequences of which are but too well known. In the present case, the wound was closed at its middle with one ligature, and the parts were dressed by the method of occlusion.

This application of linear crushing must be confessed to be peculiarly unattractive; it is laborious, complicated, protracted, and for the brilliancy of the operation can sustain no comparison whatever with the rapid method of enucleation denominated by M. Jobert de Lamballe, removal by transfixion (*ablation par embrochement*). The important point, however, is to ascertain if its results are more advantageous. M. Chassaignac's operation is clearly preferable to the section with the knife, inasmuch as it preserves the patient from the chances of secondary hæmorrhage, and lessens the perils of traumatic fever; but in order to secure these benefits and its superiority over the usual method, the precautions indicated above must be carefully attended to. M. Chassaignac further acknowledges, with his usual candour, that with regard to the excision of large subcutaneous growths—such as lipomas, tumours of the breast, &c.—linear crushing has not yet given sufficient proofs of its definitive value.

It is not so for cancer of the tongue or penis, for erectile tumours, hypertrophy of the cervix uteri, or hæmorrhoidal growths. In these affections, the *écraseur* is, unquestionably, a most efficient instrument, and none but those who have adopted foregone conclusions against all innovation can shut their eyes to the great advantages of this method.

Among the patients produced in the operating theatre we noticed a man who had long suffered from a hæmorrhoidal excrescence, which kept up a permanent catarrhal condition of the rectum, and a mucous and semi-sanguinolent diarrheic discharge. Frequent successive attacks of hæmorrhage had brought on anemic discolouration of the tissues, and the subject was gradually losing strength and flesh. An operation was requisite, which M. Chassaignac performed, adopting, however, a modification of the usual procedure, which it is useful to describe, inasmuch as it meets very serious objections urged by an eminent Professor against the destruction of piles by linear crushing. M. Nélaton stated during the present year, at one of his lectures, that he had seen patients who had been relieved by the *écraseur* from the presence of very inconvenient hæmorrhoidal tumours, but who, several months after the operation, experienced such extreme difficulty in defecation, that the stricture of the anus, resulting from the procedure, caused them to regret their former malady. This disadvantage, which is fortunately of rare occurrence, is, however, but too true, and conveys a lesson by which M. Chassaignac has profited. When crushing was first resorted to for the excision of piles, M. Chassaignac was in the habit of removing the entire tumour, and adopted the same plan for those hæmorrhoids which, seated at the margin of the anus, are partially covered with skin. The

excision of this portion of their cutaneous envelope gave rise to the formation of an extremely retractile cicatrix, which readily degenerated into progressively increasing coarctation. This unpleasant result is henceforward not to be feared; M. Chassaignac now removes circularly but the hæmorrhoidal apex, a procedure sufficient to secure a satisfactory issue. It has also been asserted, with truth, that here the *écraseur* gives no security against primary hæmorrhage. One of M. Chassaignac's patients died from this cause; but it should be observed that the spleen of this man weighed no less than thirty-two pounds, a circumstance which doubtless should have been ascertained by previous examination, but which is certainly very unusual. It may further be inquired if, in the schedule of all methods, some such catastrophe is not occasionally to be found registered. For our own part, we have witnessed very many operations with M. Chassaignac's instrument, and with the exception of a few drops of blood oozing from the spots in which the hooks were fixed, we have in general seen scarcely any hæmorrhage whatever.

Phymosis is also a condition for which the *écraseur* is appropriate. A young man, presenting this deformity, was operated on with this instrument with remarkable precision and dexterity. Anæsthetic sleep having been induced, and that degree of insensibility existing which M. Chassaignac denominates tolerance, the operator inserted into the prepuce the common dressing-case forceps, and its parted blades allowed of the thumb being placed in front of the glans, as a guide to a trochar, with which the part was perforated. The canula of the trochar was left *in situ*, and the chain-saw divided the prepuce between it and the glans penis. Not a single drop of blood escaped during this rapid section. The skin and the mucous membrane were then united with a few silver wires, a useful American importation.

M. Chassaignac's last patient was a tiler, who presented in front of each patella a hard mass, of the shape of a large flat pebble. These tumours, perhaps resulting from protracted pressure—a circumstance to which the man was much exposed from the nature of his craft—belonged to the class of enchondroma. M. Chassaignac opined that, in a region where the most unimportant operations may give rise to dangerous suppuration, it was highly desirable to resort to the procedures which expose the least to traumatic perils. He therefore performed with the knife a vertical section of the integument, and endeavoured to enucleate the growths with the *écraseur;* they were found, however, so firmly connected by fibrous adhesions with the subjacent structures that complete extirpation could not be effected. We shall watch the progress of this patient, and refer to his case if necessary. In another article we shall examine some of the applications of drainage to surgical disease.'—'Journal of Practical Medicine and Surgery.'

GLYCERINE IN AFFECTIONS OF THE EYE.

M. Foucher, Surgeon to the Neckar Hospital, makes great use of this substance, whether applied alone or as an excipient for more powerful agents. Employed alone, it is very useful applied four or five times a day to the edge of the eyelids, in order to prevent the formation of crusts,—M. Foucher attaching great importance to keeping these parts perfectly clean. He also has it rubbed into the outer surface of the eyelids, in order to maintain their suppleness; and he applies a layer to the inner surface, after he has pencilled this with the nitrate of silver and neutralised the canstic by a saline wash. The following are his usual formulæ in the proportions for 30 parts of glycerine each: 2 to 4 parts of borax; 1 to 3 of sulphate of zinc; 1 to 4 of sulphate of copper; 4 to 8 of tincture of iodine; 1 to 4 of perchloride of iron; 2 to 4 of tannin; 2 to 4 of calomel; or 2 to 4 of opium wine. In simple mucous or catarrhal conjunctivitis, the zinc or tannin formula is very useful, being often substituted for one of nitrate of silver; and, when there is abundance of mucus secreted, the inflammation not being intense, the borax collyrium is very useful. In ciliary blepharitis, as in all the inflammations of the free edge of the eyelid, the calomel or iodine collyrium should be preferred. It is in these cases that the glycerine proves so useful in preventing the formation of palpebral crusts. In superficial ulcer of the cornea, the corneitis being already somewhat subdued, the tannin collyrium is indicated; while when the photophobia is very intense, the laudanum collyrium usually relieves it. Vascular keratitis may be treated either with the tannin or perchloride of iron collyrium; but M. Foucher is not so strong an advocate of this last preparation as are some other Surgeons. In granular conjunctivitis, the copper collyrium may be advantageously substituted for the solid sulphate, and it causes less pain.—'Moniteur des Sciences Méd.,' No. 91, and 'Medical Times and Gazette.'

Births, Marriages, and Deaths.

BIRTHS.

GELL.—October 19, at Carr hill, Gateshead-on-Tyne, the wife of Alfred Scott Gell, Esq., M.R.C.S. Eng., of a daughter.

MAUNDER.—November 5, at New Broad street, the wife of C. F. Maunder, F.R.C.S., of a son.

PUGH.—October 19, at Pwllheli, Carnarvonshire, North Wales, the wife of Hugh Lewis Pugh, M.R.C.S., of a son.

ROUTH.—November 4, at Montague square, the wife of C. H. F. Routh, M.D., of a daughter.

MARRIAGE.

COMPTON—PIGOU.—November 1, at Christchurch, Paddington, Captain D'Oyly Trevor Compton, Bombay Army, to Clara Elizabeth, widow of the late W. H. Pigou, Esq., Surgeon on the Bombay Establishment.

DEATHS.

BUIST.—Dr Buist, of Bombay, of dysentery.

DUNCAN.—October 17, at Richmond, Surrey, the wife of Thomas Duncan, M.D., of a son.

MAULT.—At sea, off Pernambuco, on board the ship 'Antipodes,' Samuel Mault, late of Fenny Stratford, Buckinghamshire, M.D. St Andrews, L.R.C.S. Edin., aged 35.

MYERS.—October 26, at Prospect place, Deal, George Myers, late of Sandwich, Kent, M.R.C.S. Eng., L.S.A. Lond., aged 53.

PRIDHAM.—October 30, at the Crescent, Taunton, Somersetshire, Edward Parker Pridham, formerly of Exeter, M.R.C.S. Eng., aged 70.

SOLLY.—September 18, the wife of Edward Solly, Esq., F.R.S., of a daughter.

TAYLOR.—October 30, at Tamworth, Joseph Taylor, Esq., M.R.C.S., late of Appleby, Leicestershire, in his 70th year.

WILDEY.—October 31, at Marine terrace, Southsea, Hants, Wm. Wallace Wildey, of Cosham, Portsmouth, M.D. St Andrews, M.R.C.S. Eng., L.S.A. Lond., Surgeon R.N. (seniority, January 14, 1857), late Assistant-Surgeon Royal Marines, aged 38.

WILLS.—October 30, at Upper Islington, Elizabeth Archer Wills, relict of the late William Wills, L.S.A., in her 69th year.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, November 1:—Robert Henry Spencer Carpenter, Durham; Charles C. Mitchinson, Royal Lancashire Artillery Militia; Frederick John Sutton, Ilminster, Somerset.

APPOINTMENT.—Mr Francis J. Bailey has been elected Honorary Surgeon to the Liverpool School for the Deaf and Dumb, in the place of James B. Nottage, Esq., resigned.

DR FORBES WINSLOW has been elected President of the Medical Literary Society of London.

ROYAL INSTITUTION.—The resignation (on account of ill-health) of the Rev. John Barlow, honorary secretary for eighteen years, was announced at the general monthly meeting held on the 5th inst., and was received by the members with sincere regret.

EPIDEMIOLOGICAL SOCIETY.—At the opening meeting of the eleventh Session of this Society, held on Monday last, Dr Babington, the president, delivered the introductory address, in which, after alluding to the loss which the Society and the public had sustained in the death of Mr Alexander, C.B., Director-General of the Army and Ordnance Medical Department, and of the lamented Dr Addison, he proceeded to a general review of the main epidemics that had prevailed in various parts of the world during the past year.—Dr McWilliam then read a paper, by Professor Simpson, of Edinburgh, entitled, "Notices of the Appearance of Syphilis in Scotland during the latter years of the Fifteenth Century." An abstract of this most learned and interesting paper will appear in an early number of this journal.

UNIVERSITY COLLEGE, LONDON.—The Council held their first Session for this current academical year on Saturday last, Mr Grote, F.R.S., Treasurer, in the chair. The Professorship of Botany, vacated at the close of the last session by the retirement of Dr Lindley, was filled up by the appointment of Mr Daniel Oliver, jun., F.L.S., Librarian to the Royal Gardens, Kew. The Longridge Prize of £40, for general proficiency in Medicine and Surgery, was awarded to Mr Wm. John Smith; and the Liston Gold Medal, for reports and observations on the Surgical cases in the Hospital, to Mr William Hickman.

SIR HANS SLOANE was the first Physician in this country who received the title of Baronet, the highest title to which his successors have ever yet arrived in England. Sloane was very rich; he was Lord of the Manor of Chelsea.

SPECIALTIES IN THE UNIVERSITY OF BOLOGNA.—A Chair for the clinical teaching of Venereal and Cutaneous Diseases has been established in the University of Bologna; and Dr Gamberini, well known both at home and abroad for his writings on Syphilis, has been appointed its first Professor.

SUPPRESSION OF THE SAVOYARD UNIVERSITY SCHOOLS.—A decree, published in the 'Moniteur,' suppresses the University Schools of Theology, Law, Medicine, and Pharmacy, established at Chambery, Nice, Annecy, St Jean-de-Maurienne, Moutiers, Bonneville, and Thonon, declaring that diplomas of Doctor in Medicine and Pharmacy, obtained at Sardinian Universities prior to January, 1861, by persons natives of Sardinia,—and henceforth by annexation Frenchmen,—will be considered as equivalent to French diplomas.

THE MIDLAND MEDICAL SOCIETY.—This Society, we are glad to hear, has been re-organised under the Presidency of Dr Fleming, with the view of affording to the Profession in the Midland district the means of contributing to the advance of the science of Medicine, and, what is much needed, an opportunity of free access to its literature. Already a large library of books and periodicals is in use. The reading-room is open daily. Meetings are held twice a month in Birmingham (from October to May inclusive) for the reading of scientific papers, and the relation of instructive and important cases. The subscription is one guinea per annum.

THE HOTTENTOT VENUS.—The peculiar virtues of the Hottentot Venus of past notoriety have again been discussed and dissected by Dr Lambl, who has discovered an anomalous condition of the lumbar vertebræ in her kind, whereby the posterior protuberances are explained. This discovery, however, is stated by others to be imaginative; and the old opinion, therefore, still holds firm, viz., that the aforesaid protuberances are fatty masses—pure and simple. The objectors' position is maintained (in part) by reference to "two female Bosjesmans, who, thirty years ago, were offered for sale in Paris by English speculators on the strength of their portrait," which was subjected to the attention of any Parisian Barnum.

SISTERS OF MERCY IN EDINBURGH.—A large house is building in one of the new streets at Lawriston for a number of Sisters of Mercy, at a cost of about 5000*l*.

CHOLERA IN INDIA.—Letters from India inform us that the cholera has made its appearance at Lucknow amongst H.M. 2nd Dragoon Guards, and that several cases have terminated fatally. Large numbers of natives have also died.

A GALLANT HOSPITAL APPRENTICE BEFORE THE TAKU FORTS.—Here Lieutenant Gye, of Milward's Battery, a most promising young officer, son of the director of the Royal Italian Opera, was shot through the thigh. A gunner was wounded almost at the same moment. A lad of fifteen, on the Indian Medical Establishment, a soldier's son, and Fitzgibbon by name, was on the field as Hospital apprentice, attached to the 67th. Without a moment's hesitation he rushed to the artilleryman and dressed his wounds under a tremendous fire. In so doing he was shot in the arm; but the bullet has been extracted, and the wound is healing. A more gallant lad never lived. His character is excellent, and he well deserves some promotion.

HOSPITALS OF GARIBALDI.—I have been making the round of the principal hospitals of the city to-day—that is to say, of the SS. Apostoli, the Incurabili, the Trinita, and the S. Sebastiano, and wherever I made the inquiry I found the same complaints made of theft, wholesale and retail. In one hospital, particularly, the governor said to me, "I lose my head, sir; I have found the hospital attendants going off with two or three shirts on, with sheets rolled round their bodies. Last night we found one

man going off with three military caps. Bread, wine, meat—everything is stolen; the very soup, after it is taken from the kitchen, is watered by the way, a portion of the good soup having been abstracted. Even the drugs are adulterated, and a commission appointed at my instance to examine them found the quinine had been mixed, and to this I attribute the loss of two of the fever patients. Three men are in the forts, under accusation; forty-eight I turned off yesterday. Yet the Intendente-General continues to send men who are only fit for the galleys, and whose great object is plunder. Do you know, sir, that, according to the accounts which have been made up, it has cost this month a piastre a day for each man (a piastre being a fraction less than 4s.)?" The Governor told me—and I fully acquiesce in what he said—that the only plan to be adopted was to sweep off the present staff, and introduce as much of the northern element as possible. The Piedmontese and Milanese hospital attendants are admirable, though their number is insufficient. It occurs to me, however, that much more might be done with what materials are at hand; and, in the hope that the suggestion may meet the eye of some who are interested in the hospitals of Garibaldi, I would propose that an inspector, a Piedmontese, be chosen from these men to watch over the organization of matters in every ward. Unless this be done, I am persuaded that the same system of plunder will be continued, and the same disorder and filth. The Dictator visited the S. Apostoli last week, and honourable mention is made of it in a letter written by him and published in the official journal. Though better than the others, it is by no means free from the evils of which I speak. That of S. Sebastiano, which I have more frequently visited than the others, and where our countrymen are quartered in Naples, is more open to complaint; but it cannot be judged by the same standard, as it is an *improvisé* hospital, and everything has to be arranged.—Naples Correspondent of the 'Times,' Nov. 2nd.

Belfast Branch of the Medical Benevolent Fund Society of Ireland.—The usual quarterly meeting of the Belfast branch of the above most praiseworthy and excellent society was held on the 5th inst. in the Library Room of the Belfast Medical Society—the chair being filled by Dr Patterson, in the unavoidable absence of Dr T. H. Purdon, the permanent President. A report was made by Dr Stewart, the secretary, of the several sums distributed to this branch by the Parent Society, at its last annual meeting, which were very liberal, considering the limited resources at command, coupled with the unhappily large number of pensioners on its bounty. The nobility and gentry, if not the public generally, who owe so much to the Medical Profession, are naturally looked to for more generous aid than hitherto they have afforded to a society which has been effecting so much good, even crippled as it is in its means; but it is to be hoped that the bright example set by the reigning monarch in increasing the funds of the society will be extensively followed by her wealthy and exalted lieges, whose privilege it should be to aid in the helping forward of so righteous a cause as this society is the representative of. The members of the Profession itself should, at the same time, do its duty irrespective of extern aid, no matter how well deserved, and put their own shoulder to the work unitedly and effectively, so as to make the lot of their less fortunate brethren more bearable, and their own all the happier and more prosperous by thus acting on their behalf. Arrangements having been made for the ensuing annual meeting of subscribers, and some other routine business transacted, the meeting separated.

APPOINTMENTS FOR THE WEEK.

Wednesday, November 14.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.
Hunterian Society.—Council Meeting, 7½ p.m.—Mr Solly, "On a Case of Farcy," 8 p.m.
North London Medical Society.—Dr Part, "On a Case of Poisoning by Strychnia, in which Treatment was Successful," 8 p.m.

Thursday, November 15.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.
London Surgical Home.—2 p.m.
Harveian Society.—Discussion of Clinical Cases, by Dr Pollock and Mr Weeden Cooke, 8 p.m.

Friday, November 16.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.
Western Medical and Surgical Society of London.—Practical Evening for the Narration of Cases and Exhibition of Specimens.—Dr Fincham, "On a Case of Renal Abscess, accompanied by some Anomalous Nervous Symptoms."—Mr Leggatt, "On a Case of Acute Glossitis." 8 p.m.

Saturday, November 17.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, November 19.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.
Royal Institution.—2 p.m.
National Hospital for the Paralysed and Epileptic.—Clinical Lecture on "Epilepsy and Paralysis," by Dr Brown-Séquard, 4 p.m.
Medical Society of London.—8½ p.m.

Tuesday, November 20.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

On Syphilitic Diseases. By Langston Parker, F.R.C.S. Fourth Edition. London: John Churchill.
On Surgery. By Wm. Pirrie, F.R.S.E. Second Edition. London: John Churchill.
Strychnine and Nicotine. By the Rev. Samuel Haughton, M.A.

NOTICES TO CORRESPONDENTS.

Mr B. Johnson.—1st. The New Edition of the 'Medical Directory' will contain all the information you require.
Medicus.—We believe that all the vegetable parasites are identical,—at any rate, no important difference has yet been established between them. The difference in the morbid states may be accounted for by the different sites and structures implicated in the affection. The best treatment is to improve the health, and kill the parasite. The books give the necessary information on these points.
J. H. B.—Certainly.
An Old Subscriber.—You have no redress under the circumstances. Your only course is to dissolve the partnership. If your partner decline to buy your share, you can sell it to a stranger, whom he cannot refuse to accept.
Omega.—The Report of the Inquest has been received.
Mr C.—The letter on the Lunacy Act, and the duties of Poor-law Surgeons with reference thereto, received.
Islingtoniensis.—The handbill is a very disreputable document; but if the author has no respect for the opinion of his neighbours, he will not have much for ours.
Mr Gill.—Forwarded.
Mr B. Jones.—It shall be attended to.
Mr J. H. Smith.—You should communicate with the Editors of the 'Directory,' stating qualifications and appointments.
A Lover of Fact says that in a short leader in the 'Medical Times and Gazette,' it is stated that a paper was read at the Epidemiological Society, "On the Introduction of Syphilis into Scotland, by Professor Simpson," and, adding that as he was not aware that Scotland was exempt from syphilis until the last quarter of the century, wishes to know if it be really a fact that Professor Simpson deserves the reproach of having introduced syphilis into Scotland,—and was it done by syphilization, or how?—If our correspondent read the article a second time, he will see that there is a false construction in the article, which has led to the false construction of our correspondent. The writer meant to say that the paper was read by Professor Simpson. The best writers blunder sometimes,—why not, therefore, our contemporary?
Pinguis.—1st. No.—2nd. We cannot advise.
Mr Peter B.—Certainly.
Mr Walker.—Received.
D. R. wishes to know which is the best of the numerous respirators invented? Perhaps one of our readers will be able to supply the information.
A Constant Reader (Bath).—The Preliminary Examination at Apothecaries' Hall is *compulsory on all candidates who commenced their apprenticeship on and after the 1st of August*, 1858. It embraces classics and mathematics. The subjects of examination are announced three months before each examination. We are, therefore, unable to specify beforehand the special subject of the examination.
Dr Stewart.—Received.
L.R.C.P.—Our opinion is that a Licentiate of a College of Physicians is justified by use and custom in using the title of "Doctor." It is not likely that the proposed New Charter of the College of Physicians will prohibit the use of the title. Such an assumption would be *ultra vires*.

PULVIS JACOBI *VER.*, NEWBERY'S.

To the Medical Profession of Great Britain and Ireland.

Gentlemen,—We beg to call your attention to the following extract from a Paper by the late John Cheyne, M.D., F.R.S.E., M.R.I.A., Physician to the Hardwicke Fever Hospital, Dublin; and Physician-General to His late Majesty's Forces in Ireland, &c., &c., contained "*in the Dublin Hospital Reports*," *vol.* i., *p.* 320.

"The following very simple method of "exhibiting JAMES'S POWDER, in cases "of undue determination of blood to the head, "is that which I have generally pursued. The "patient is made to begin with a very moderate "dose, not more than two grains at bedtime, "and to increase the dose by half-a-grain every "night, until some sensible effect is produced "upon the stomach, bowels, or skin. Should "the stomach be affected with sickness, the dose "must be lessened, by one grain on the following "night. By the addition of a little rhubarb "to it, a larger quantity of JAMES'S "POWDER may be administered than the "stomach could otherwise bear. If the skin "is softened, or the bowels affected, the dose "should not further be increased, burt it must be "repeated every night for a considerable length "of time: in several instances I have known "eighteen or twenty grains taken for a consi-"derable period without any inconvenience."

To secure the dispensing of the *original* preparation, which, for 114 years, has been sold by the house of Newbery and Sons, in St. Paul's Churchyard, it is necessary to prescribe it as "Pulvis Jacobi Ver., Newbery's," otherwise another article (wanting in the best properties, and recommended to be given in a different code of dose, *though called by the same name*), may be substituted for the original medicine.

This substitution must bring disappointment, and of course lead Practitioners to give up prescribing Dr. James's Powder altogether, or to regard it as a preparation on which no dependance can be placed.

FRANCIS NEWBERY AND SONS
45, St. Paul's Churchyard, London.

Prices for Dispensing ¼ oz. Bottle 3*s.* 4*d.*, 1 oz 9*s.* Usual Discount to the Profession.

A CUP OF COFFEE IN ONE MINUTE.

Dunn's Essence of Coffee,

warranted to keep good in any climate.

This Essence of the finest kinds of Coffee, improved by a process the result of the experience of more than half a century, contains all the fragrant and exhilarating properties of the coffee in the highest perfection. It is admirably adapted to persons travelling, and to Officers in the Army and Navy.

Extract from the Commercial Handbook of Chemical Analysis, by A. Normandy, M.D.: "Coffee is met with in commerce as a manufactured article in the state of Essence, or rather Extract of Coffee. That preparation, providing it be genuine, is peculiarly adapted to the use of travellers, who are thus enabled to procure a cup of good Coffee without trouble or apparatus. Of all the attempts which have been made to manufacture such an Extract, and of most of which I have had samples, I have found on examination that only one kind, that manufactured by DUNN, of Pentonville, would keep.

"I think I can confidently assert that DUNN'S Essence of Coffee is the only one which has stood ground; all other attempts, for some reason or other, have hitherto proved failures, and eventually have been abandoned."

Sold in bottles, from 1s. to 2s. each.

DUNN'S UNADULTERATED CHOCOLATE AND COCOA.

DUNN'S CHOCOLATE BON-BONS, CHOCOLATE DROPS, CHOCOLATE STICKS, etc., and every kind of French Chocolate.

All articles manufactured by the Firm of DUNN and HEWETT are guaranteed free of adulteration under a penalty of £50, to be given to some charitable institution, if found at any time adulterated, under certificate of Dr Normandy, Analytical Chemist to the House of Commons.

Manufactory, Pentonville, London.—To be had of all Grocers.

Chlorodyne.—R. Freeman,

Pharmaceutist, Kennington road, London, S., informs the Profession and Trade that he has FOR YEARS MADE, and extensively used in his business, Chlorodyne; and that he is supplying it in one-ounce stoppered bottles at 1s.6d. each, and in four-ounce bottles, 5s. each. He guarantees it to be uniformly and properly prepared, and superior to any other makers', though their charge be ever so exorbitant; and he trusts that the lowness of price at which he offers it will allow the Profession to use it in common practice and at public institutions, so that its extraordinary beneficial effects may be enjoyed by the poorest sufferer. Sold by all Wholesale Druggists.

WATER MATTRESSES & CUSHIONS,

For Bed Sores, Consumption,

Paralysis, Fevers, and all Invalids and Bedridden Patients. Air Cushions and Pillows, Bed Sheets, Elastic Stockings, Enemas, Ear Trumpets, Railway and Bed Urinals, Bed Pans and Slips, &c.

WILLIAM LEE, 115, NEW BOND STREET, W.

Water Beds on Hire, 7s. per Week. Deposit, £10.

DINNEFORD'S

Pure Fluid Magnesia,

now greatly improved in purity and condensation. "Mr Dinneford's Solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

This excellent remedy, in addition to its extensive sale amongst the public, is now also very largely used for DISPENSING. In the stone jars (half-gallon, 5s. 6d.; gallon, 9s. 6d.,) specially adapted for the use of Surgeons and Chemists. To be had from the Manufacturers.

DINNEFORD and CO., Chemists, 172 Bond street, London; all Wholesale Druggists and Patent Medicine Houses.

Antimargaric Cod-liver Oil,

Pure and Tasteless, sold by H. ELDREDGE, Wholesale Agent, for Messrs WM. & EBENR. ROTTON, at their Depôt, 85 Pentonville road, London, and by most respectable Chemists throughout the kingdom.

This Oil, extracted by W. and E. ROTTON, possesses all the medicinal properties essential in cases of Consumption, Diseases of the Chest, Infantile Wasting, general Weakness, &c.; and for many ills the human frame is heir to, there is not its equal. In order to prove its superiority over every other, it has been subjected to the most scientific Analysis, as proved by Testimonials received from the following well-known Physicians:—WM. HERAPATH, F.C.S., of Bristol; JOHN POSTGATE, M.D.; DR BELL FLETCHER, M.D.; D. W. CROMPTON, M.D.; WILLIAM SANDS COX, Senior Surgeon of the Queen's Hospital, Birmingham; and many others of equal eminence.

DR SEPTIMUS GIBBON, A.B. & M.D., Medical Officer of Health, late Professor of Natural Philosophy at St Bartholomew's Hospital, Physician to the London Hospital, &c. &c., of No 3 Finsbury square, London, E.C., whose recent investigation under Government brought to light such an alarming extent of adulteration in articles of diet, writing expressly upon Messrs W. & E. ROTTON'S Antimargaric Cod-liver Oil, uses the following expressions:—

"I have carefully examined some bottles of Messrs W. ROTTON & SON'S Cod-liver Oil, and find them to be excellent samples of pure Oil. Besides answering admirably to the usual tests, it is free from the noxious and nauseous principles, Margaric Acid, &c., which so commonly render Cod-liver Oil not only unpalatable, but indigestible and injurious to the human stomach. By their mode of extracting and preparing this admirable remedy, I feel satisfied they have overcome the main obstacle to its more frequent and general use in medical practice."

The Antimargaric Oil is sold in pint bottles at 2s. 6d.; half-pint, 1s. 3d.; quarter-pints, 8d. Where a difficulty is found in obtaining it, write direct to the Depôt, when a case will be forwarded for the amount of 5s. or 10s., carriage free.

None is Genuine unless Capsuled, and Signed WILLIAM and EBENEZER ROTTON.

WATER BEDS AND CUSHIONS.

A Preventive against Bed

Sores, &c. Bed Sheets, Air Cushions, and all necessary Utensils for Invalids.

BENHAM and Co.,

S. Bowles (late Windsor and

Co.), PHIAL and BOTTLE MERCHANT, Dealer in Druggists' Sundries, &c., 6 James street, Covent garden, W.C. The cheapest house in London for every description of MEDICAL GLASS of the best quality.

Samples and prices forwarded free on application.

To Gentlemen.—Mr Miles,

(Alfred Webb Miles,) Established 18th February, 1841,

Originator of the WORLD-FAMED TROUSERS, at 16s. per pair, has the pleasure to inform thirty thousand customers that his stock for the forthcoming Winter is now replete with all the new and best designs for Over-Coats, Morning and Travelling Suits, Vests, Trousers, at prices as heretofore. Gentlemen who have not already favoured this establishment with their interest and support are most respectfully informed that it is distinguished not only by the extent, variety, and quality of its patterns and materials, but it excels in the cut and workmanship.

CAUTION.—Mr Miles is not connected with any person imitating and advertising in the same name; his only address is 73 Brook street, Hanover square, and he has no other establishment in London or elsewhere.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

32 SOHO SQUARE, LONDON, W.
October 22nd, 1860.

Notice.—The Copy of the

MEDICAL REGISTER to be printed and published in 1861, as directed by the 27th Section of the Act, will contain those NAMES only which appear on the General Register as existing on the 1st day of January, 1861.

It is particularly requested that claims for the Registration of first or additional Qualifications, and Notices of Alteration of Residence, may be sent to this Office as soon possible.

United Kingdom Life

ASSURANCE COMPANY, No. 8 WATERLOO PLACE, PALLMALL, LONDON, S.W.

The Funds or Property of the Company, as at 31st of December, 1858, amounted to £652,618 3s. 10d., invested in Government or other approved Securities.

CHAIRMAN.—The Hon. FRANCIS SCOTT.

DEPUTY-CHAIRMAN.—CHAS. BERWICK CURTIS, Esq.

INVALID LIVES.—Persons not in sound health may have their lives insured at equitable rates.

ACCOMMODATION IN PAYMENT of PREMIUMS.—Only one-half of the Annual Premium, when the Insurance is for life is required to be paid for the first five years, simple interest being charged on the balance. Such arrangement is equivalent to an immediate advance of fifty per cent. upon the Annual Premium, without the borrower having recourse to the unpleasant necessity of procuring Sureties, or assigning, and thereby parting with his Policy, during the currency of the Loan, irrespective of the great attendant expenses in such arrangements.

The above mode of Insurance has been found most advantageous when Policies have been required to cover monetary transactions, or when incomes applicable for Insurance are at present limited, as it only necessitates half the outlay formerly required by other Companies before the present system was instituted by this Office.

LOANS are granted, likewise, on real and personal Securities.

FORMS OF PROPOSALS, and every information afforded, on application to the Resident Director, 8 Waterloo place, Pallmall London, S.W.

(By Order) E. LENNOX BOYD, Resident Director.

Newton Wilson and Co.'s

World-famed PATENT.—THE NEW PATENT NURSING CHAIR, in which the child nurses, amuses, exercises, and weighs itself, is a marvel of ingenuity and utility, unanimously recommended by the Press and the Faculty. No family should be without one. Price 12s. 6d. upwards. Prospectus free.

WILSON'S PATENT CARPET SWEEPER, which cleans a carpet thoroughly without labour, without injury, and without raising a grain of dust. Price 15s.

Newton Wilson and Co., 144 High Holborn, London.

Important to Surgeons.—

The old-established and well-known Business of JOHN MILLIKIN, now MILLIKIN and LAWLEY, 161 Strand, adjoining King's College.—A change in the proprietorship offers to Surgeons the opportunity of purchasing any kind of Instrument from this well-manufactured stock, which cannot be surpassed in style, quality, or price.

Messrs MILLIKIN & LAWLEY beg to draw the attention of their friends and customers to the superior stock of Mathematical Instruments, their great variety of Cutlery, and the selection of first-class Microscopes, Opera and Race Glasses.

A great variety of Skeletons, Skulls, Hands, Feet, &c., of superior quality, at moderate charges.

Every description of Surgical Instruments made to order, with the utmost PRECISION and DESPATCH.

Surgical Instruments and Cutlery Repaired Daily.

Liquor Castanea Equina.—

Messrs. REW and Co. respectfully solicit the attention of the Profession to this Preparation of the Horse-Chesnut; taken internally for Rheumatic Gout and Rheumatism, it is a safe, agreeable, and most efficacious remedy.

Dose, two to four drachms. Price 12s. per pound.

The Oil of Horse-Chesnuts applied externally for enlarged and stiff joints, acute or inflammatory pain of any kind, gives almost immediate relief.

These genuine Preparations of the Horse-Chesnut are prepared only by REW and CO.

LITHIA WATER, LITHIA POTASH, and LITHIA AMMONIA WATER. These Waters are prepared according to the Instructions of Dr Garrod, and each bottle is guaranteed to contain the proper proportion of Lithia. 5s. per doz.

R. M. REW and CO., Operative Chemists, 282 Regent street, London.

The Roman Thermo-

ELECTRICAL BATH. By J. TUCKER, M.D.

Price 6d., from the Author, at Sligo.

CLINICAL LECTURES.

ON DISEASES OF WOMEN.

DELIVERED AT ST THOMAS'S HOSPITAL,
By CHARLES WALLER, M.D., Obstetric Physician to the Hospital.

Lecture III.—On Pelvic Inflammation and Abscess.

(Continued from page 302.)

I purpose this morning, gentlemen, to direct your attention to a form of disease, specimens of which you have lately had the opportunity of seeing in Ann's Ward. It is an affection not uncommon, and productive of a great amount of suffering. Like inflammation attacking the cellular membrane in other parts of the body, it may speedily end in what is called resolution, in which case all symptoms of inflammatory action subside without leaving any traces behind; or it may proceed a stage farther, and a tumour of considerable size form, hard to the touch and well defined, which may remain for months after all the active symptoms have disappeared. I believe that many chronic pelvic tumours arise from this cause. Or, lastly, the suppurative process may be set up, and an abscess of greater or smaller size be formed (attended with all the constitutional and local symptoms of purulent formations), which will make its way to the most convenient locality for its discharge. Sometimes it points outwards, passing through the abdominal parietes: more frequently, however, adhesion takes place either to the vagina or rectum, the ulcerative process is set up, and the pus is discharged through one or other of these passages. In some rare cases, the walls of the bladder give way, and the pus is discharged through the urethra. There is an interesting case at the present time in Ann's Ward, in which this communication is established, and where an external opening also exists: large quantities of pus mixed with urine pass through this opening, as well as by the urethra. As a general rule, the parts heal kindly, and the patient is restored to health. Occasionally sinuses form, which are very troublesome, and the knife of the surgeon may be required. I have never in my own practice seen a case of this kind; they have, however, been recorded by others. From the peculiar hardness of the tumour, and from its proximity to the uterus, it has sometimes been mistaken for disease of that organ; and this is especially likely to happen when, from the large extent of the surrounding inflammation, the uterus is fixed and immovable, so that it appears to form part of the tumour itself. A case of this kind lately occurred to myself, the symptoms inducing me to believe that the uterus was involved in the disease; an opinion which was corrected by the bursting of the abscess; after which the organ, which had been to a considerable extent retroverted, was set free, and immediately regained its natural position. The pus which is discharged from these abscesses is of a peculiarly offensive character, probably from its being long detained within the body prior to its discharge. The symptoms in the early stage of the disease are of a purely inflammatory character; the patient complains of pain more or less acute, generally deep-seated, increased if firm pressure be made over the part affected. In some cases, even in the beginning of the disease, a certain degree of swelling may also be distinguished by the hand externally, hard to the touch and extremely sensitive. As the tumour enlarges, the organs within the pelvis suffer from pressure; there is often frequent desire to pass the urine or fæces, accompanied with difficulty in accomplishing the act. This symptom is sometimes so harassing to the patient, that the use of the catheter or enemata, or both, may be required. There is also considerable febrile excitement present: the pulse is hurried, the tongue white, the skin hot and dry; there is thirst, and commonly a severe headache. If these symptoms occur after parturition, the patient should be narrowly watched, as they are sometimes the precursors of puerperal fever, or of phlegmasia dolens. In puerperal fever, however, there is generally a distinct rigor, which is not common at the beginning of pelvic inflammation; neither is there, in the latter disease, that sudden and alarming prostration of the vital powers, whilst the pelvic pain is much more acute. The precise nature of the complaint can only be ascertained by a careful vaginal examination, when a tumour will be discovered of greater or less size (as the case may be), occupying some part of the pelvis; sometimes it is low down, pressing upon the rectum behind; or if it be situated more anteriorly, then the bladder may be affected. The circumference of the tumour can in some instances be distinctly traced, whilst in others it is out of the reach of the finger. It is painful when touched, and not so moveable as most other pelvic growths. In some cases, the swelling commences higher up in the iliac region, and can more easily be felt through the abdominal coverings than by a vaginal examination. The cause of this affection cannot in many instances be satisfactorily determined. When it occurs in the puerperal state, it has been supposed to arise from the pressure necessarily inflicted during the descent of the child. These cases, however, very often occur at other times where no mechanical injury of any kind has occurred. I believe most cases of pelvic inflammation terminate either in resolution, or in the formation of chronic tumours, which may remain for months, and then gradually disappear. Dr Simpson is of opinion that in the early stage of this inflammation, the fluid contained within the swelling is simply serum, and that pus is not formed for a considerable time afterwards. It is probable that many cases of true pelvic inflammation are relieved without the real nature of the case having been ascertained: the existence of pain, with the usual fever attendant on an inflammatory condition, leads to the adoption of mildly antiphlogistic measures, local and constitutional, and the patient gets well. Occasionally, however, pus is formed; and then those symptoms which are so commonly present where purulent deposit takes place internally speedily manifest themselves. Of these, rigors are the most prominent, attended with that peculiar febrile condition termed "hectic;" there is great prostration of strength; the tumour appears to be larger, and not so hard: fluctuation cannot always be felt, in consequence of the density of the walls of the abscess; these, however, become thinner as the disease advances, and at length the existence of fluid is ascertained without difficulty. By and bye, if the part be not punctured, an opening is effected by nature; purulent fluid is discharged, to the great relief of the patient's suffering; the quantity is sometimes very large, and, as before stated, the pus is most horribly fœtid. The treatment of these cases at the outset should be antiphlogistic, though even in the more severe forms of the inflammatory process this plan must not be carried to any great extent. A few leeches applied either to the groin, the vulva, or the anus, according to the situation of the tumour, followed by the constant application of warmth and moisture, will generally afford relief. A slight laxative should be administered, low diet enjoined, and the patient kept as quiet as possible, in the recumbent position: this latter direction, however, is almost superfluous, as, from the great pain experienced at any attempt to move, the patient instinctively avoids any bodily exertion. I recollect one case occurring in my private practice, in which the right lower extremity was *fixed;* it could not be moved either by the patient or myself: the inflammatory tumour had in this case evidently existed in the neighbourhood of the muscles passing from the pelvis to the thigh, and consequently prevented their action. This female had lately been delivered: it is probable, therefore, that the cause in this instance may be attributed to mechanical injury arising from the labour itself. Where the constitution has a strumous taint, tonics, with a moderate stimulation, should be had recourse to from the first.

Case I.—Mary Butler, æt. thirty-eight, transferred from Mary's Ward, with intense pain in the right iliac region; she has a pale, sickly, strumous appearance, and is the subject of leucorrhœal discharge. The pain extends from the iliac region to the knee; the thigh is enlarged and œdematous. A tumour of considerable size, with fluctuation, could be felt in the iliac region; to this poultices were applied. In the course of a few days, matter was freely discharged. This patient experienced extreme pain when attempting to move the lower extremity: this symptom continued for a considerable time, and even when she left the hospital free from discharge and perfectly restored to health, she had not acquired the free use of her limb. This case did not come under my notice until the suppurative process had taken place; as her constitution was enfeebled, the plan adopted was the free exhibition of tonic medicines, with corresponding diet.

Case 2.—S. Edgecomb, admitted into the hospital in an exceedingly broken-down state of health; there was such extreme exhaustion, that death seemed imminent. She had no appetite, suffered from diarrhœa, and was fearfully emaciated. See has been for a long time the subject of purulent discharge per rectum, which occurs at intervals only; there is none at present. On examination, a hard mass was felt within the pelvis, involving the uterus, which was larger than usual. I expressed a doubt whether this was true pelvic abscess, or whether matter had formed in the uterine wall. A free discharge per anum subsequently took place, and the uterus became more moveable, proving that the organ was not the seat of the disease. The patient's constitution was supported by the liberal use of stimulants, and any article of food she could fancy. The discharge ceased, and at the expiration of twelve weeks she left the hospital in perfect health, a little hard mass still remaining in the posterior part of the pelvis.

Case 3.—Eliza Pippins, æt. twenty-eight, married; has had three children—last nine weeks since: she has nursed the infant up to the time of her admission into the hospital. She felt pain in the pelvic region soon after her confinement. About two weeks ago, discovered a swelling, which has gradually increased in size. There is still much pain. On external examination, a prominent tumour was discovered in the position of the bladder, feeling very like that organ when distended with urine, except that its size was much less; fluctuation very distinct. Internally the uterus was found healthy; on the left side of the pelvis there was much hardness, with great tenderness on pressure; there have been stabbing pains, with occasional rigors; the patient has cough, and appears phthisically disposed. Ordered a linseed cataplasm to the tumour, and the following medicine:

℞ Inf. gent. co., ℥j.
Acid. nitro-muriat., ℥iij. : ter die.

The abscess soon burst, and a very large quantity of fœtid pus was discharged. This patient left the hospital, at her own request, in less than a month, the tumour much

lessened, the health improved, although there was still a little discharge from the wound.

Case 4.—Charlotte Tucker, delivered of a dead child three months before her admission; had pain in the left iliac region ever since she was delivered; no catamenial flow since about two years ago; had suppression for twelve months previously. When examined, a large hard mass was felt posteriorly, pushing the uterus forwards. The rectum was filled with hardened fæces, to remove which ol. ricini, ℥ss., was given, followed by an enema. The rectum having been emptied of its contents, the patient was again examined; the tumour still there, and tolerably well defined, ovoid in shape. In a few days, a large quantity of very offensive purulent discharge passed per vaginam. The pain and swelling were immediately lessened. She was retained in the hospital for nearly three months, and then discharged, a small hardened mass still remaining.

There are two cases which have very recently occurred, and which you have had an opportunity of seeing in the wards of the hospital, which are of an interesting character. In one the inflammation was checked, and the inflammatory tumour disappeared: in the other, the patient still remains in the house; the fistulous opening has not yet healed, the sinus communicating with the ureter or bladder.

Case 5.—S. Stringer, ætat. sixteen, admitted Aug. 20 into Magdalen Ward with gonorrhœa of three months' duration; has had no catamenial discharge since June. I was requested to see her for the first time on the 28th September, in consequence of pregnancy being suspected; the known habits of the patient, the suspension of the catamenial flow, and the enlargement of the abdomen, all combining to favour such suspicion. On inquiry, I was informed that in the beginning of August a swelling of peculiar hardness was felt in the right iliac region, which had gradually increased in size until it nearly reached the umbilicus. Her pain was sometimes agonising. On an examination internally, the uterus was found of small size, and unconnected with the swelling. The tumour externally was dull on percussion, without fluctuation, and extremely tender to the touch. A bran poultice was ordered to be applied and to be frequently renewed, and some soothing remedies administered. The pain was soon relieved by these applications, and in about ten days the tumour began to lessen, and towards the end of October had entirely disappeared, the patient having perfectly recovered her health and strength. The catamenia had not returned, and as the abdomen was still large, I made another examination on the 10th November, prior to her being discharged from the hospital. The abdominal enlargement proved to be the consequence of adipose deposit; no tumour to be felt; no increase in the size of the uterus; the mammæ, though enlarged by fatty deposit, were soft and flabby, and no areola surrounded the nipple.

Case 6.—Sarah Vaughan, æt. forty, admitted into Ann's Ward July 31. She has been married twenty-three years, and has had two children, the youngest of whom is now nineteen years of age; has been in a delicate state of health for two years; she is now exceedingly emaciated and anæmic; has no appetite; sleepless nights; does not satisfactorily pass urine, but small portions pass involuntarily during the night. A large tumour was seen externally, extending from the symphysis pubis to the umbilicus, which is somewhat protruded, as in pregnancy. There is evident fluctuation. When examined internally, the tumour was found filling up the pelvis, and pushing the bladder downwards and backwards; the catheter was introduced in a direction corresponding to the altered position of the bladder, and about 17oz. of urine, mingled with pus, were removed: the urine was highly alkaline. A tonic was prescribed, with any article of food the patient had a fancy for. Two days afterwards the abscess burst at the navel, and a large quantity of extremely fœtid pus and urine was discharged: the fluid thus evacuated was so offensive as to prove a source of great annoyance to the occupiers of the neighbouring beds; to correct this, chloride of lime was liberally used. The abscess is still discharging, and urine, though in smaller quantities, still passes by the wound when the patient is in the recumbent position; purulent matter also passes with urine, through the meatus. A large abscess formed in the perineum a few weeks after the patient's admission, which was evacuated by puncture, and was quickly cured; this did not appear to have any communication with the original tumour. Pressure, by means of a pad, confined with adhesive plaster, has been applied to the external wound, which produced much uneasiness, and was, therefore, discontinued. This patient has quite recovered her health and strength.

Case 6.—Ellen Reader, æt. thirty, married twelve years, no family, admitted a few weeks since, complaining of great pain in the left iliac region, extending through the pelvis. When examined, a large hard mass was felt through the abdominal coverings. The tumour was not easily reached by an internal examination; the uterus healthy. This case is still under treatment.

Case 7.—The last case I have to bring before your notice was one of extreme interest which I attended with my friend Mr Ward of Epsom. When I first saw her, Mr Ward informed me she had been out of health for some time, and had for months before he saw her been the subject of severe abdominal pain, which at last had become most acute, resembling that occasioned by the passing of a calculus. Narcotics relieved her, but she continued feverish and depressed. I first saw her on the 11th of July: she was still suffering from pain. On examination, the bladder was found to contain a considerable quantity of urine, which was removed by the catheter, the uterus partially retroverted, apparently enlarged, and fixed in its position. In a day or two afterwards a very large quantity of offensive pus was discharged per rectum. The symptoms were immediately relieved. The discharge continued for some weeks. When last seen by Mr Ward, there was a tumour of small size remaining. The uterus had returned to its normal position after the bursting of the abscess.

PATHOLOGY OF THE SYMPATHETIC NERVES.

By JAMES RORIE, M.D.

II.—Centric Paralysis (Fever).

(Continued from page 319.)

"Along with the relaxation of the skin, the tongue, if before dry, begins to moisten, in consequence of the returning secretion of mucus and saliva. The fur on the tongue also begins to be removed, and the surface of that organ to assume the healthy colour." The pulse now gradually becomes less frequent the thirst and disinclination for food subside the appetites return, and the patient slowly assumes his former health.

The course of a fever given above is chiefly extracted from Wood's 'Practice of Physic,' and may therefore be looked upon as a correct enumeration of the most important phenomena. Such being the facts, let us now consider how far they can be explained by our theory.

An agent capable of producing the above-described febrile condition (the hypothetical, poison) enters the system, and specially affects the sympathetic centres. And here let me remark, no exception can be taken to this specialty of action; for therapeutics teach that certain poisons may and do act on some portions of the nervous system, and leave others unaffected. Now, we have formerly seen that the first action of an irritant is increase of function of the part to which the nerves are distributed. We therefore here expect the same change—and such we find to be the case. The sympathetic centres are first affected by the poison, and the excitement produced slowly extends over all the filaments which leave these centres. We have, therefore, contraction of the arteries and capillaries induced, slowness of the heart, and peristaltic action of the arteries. In this manner results the so-called "depressed circulation." But, in consequence of the contracted state of the vascular system, and the slow action of the heart, &c., the chemical changes between the blood and tissues are prevented, and a diminution of heat is produced; and it is worthy of notice, that this is first felt at those parts of the body nearest the sympathetic centres. Hence, we find that this "coldness and shivering begins in the back, and extends over the whole body, reaching the limbs last." These changes, moreover, all tend to produce a contracted state of the whole body; hence, "the face is pale, the features often shrunk, and the skin generally pale and contracted;" and this contraction may even reach such an extent as to produce "a purplish or bluish appearance in the hands and feet, &c."

Again, the chemical changes between the blood and air in the lungs take place only to a very slight extent, from the small surface of blood exposed, in consequence of the contracted state of vessels, &c.; so that (contrary to what might at first be expected) "the respiration is short and somewhat hurried, and both the breathing and pulse are accelerated by muscular exertion." The brain is also, along with the other organs, but imperfectly supplied with blood; hence arises "the pain in the head, giddiness, and mental confusion;" not, however, the pain and sense of fulness of the second stage, but pain and mental disorder such as we find in anæmia. The pain in the back and limbs, no doubt, depend on similar changes occurring in the spinal cord.

In consequence of this imperfect circulation of the blood, we have also cessation of all secreting glands, "a dry and clammy state of the mouth and fauces," imperfect secretion of urine, &c.

It is evident that at this stage the powers of the system may be so far reduced as not to rally, and death occur: but should this not happen, the poison still continues to act on the sympathetic centres, and the irritability gives way to paralysis. The second stage now begins. The nerves having lost their power, permit dilatation of the vessels, which leads, as we have already seen, to an increased production of heat, so that "a thermometer placed under the tongue may indicate a temperature of 107°." This increased flow of blood leads now to important cerebral symptoms; the face is flushed, the head painful, &c.; not the pain, however, of the first stage, but now the result of congestion. But we have seen that the sympathetic system is also distributed to the glands and intestinal mucous membrane. These will also suffer from the paralysis; so that their secretion becomes not only arrested, but perverted, and the intestinal movements paralysed. Constipation thus results, and the absence of the proper secretions allowing the feculent matter to decompose, &c., the discharges are almost always unhealthy in colour, odour, or consistence."

But although no secretion takes place, probably from deficiency of the watery element of the blood, growth is still going on; and in accordance with the law that an increased supply of blood leads to increased growth, the epidermic scales on the tongue, and probably throughout the whole intestinal canal, increase to a great extent. This also, no doubt, takes place in the glandular organs, as the kidney; for when the nerves recover their function, contraction of the vessels commences, and the watery part of the secretion is increased; the first quantities of urine, &c. are of very high specific gravity, and much loaded with matters the peculiar product of the epithelial lining of the tubes, &c.

The circumstance that this increased growth takes place when the watery portion of the secretion is deficient, and insufficient to clear the tubes, &c., and decomposing, satisfactorily explains the altered appearance of the secretions, the disagreeable smell, &c., which is observed only when the sympathetic nerves have so far recovered their function as to permit secretion, and the watery element is in sufficient quantity to wash clean, as it were, the tubes and gland-ducts.

(c) As the third stage approaches, that is, as the sympathetic system recovers its function, the heart and bloodvessels gradually return to their healthy condition, and the glands recover their usual action. The fur gradually disappears from the tongue, the growth of the epithelial particles assuming its normal standard; an increased amount of epidermic scales is also frequently thrown off from the skin; all indicative of a common cause. When the fur separates from the tongue in patches, leaving it glassy, this process is analogous to the eparation of the cuticle in small blisters, or sudamina, and also to the desquamative nephritis so frequently occurring after scarlatina.

"Occasionally one or more abscesses form in various parts of the body,"—this is a phenomenon worthy of remark. Some writers regard it as one of the means by which the poison is got rid of, although we have no evidence of their containing more poisonous matter than the other secretions. I am, however, rather inclined to look upon it as the result of the paralysis having in these parts become permanent, instead of being merely temporary, and, as we have seen while treating of inflammation, leading to the death of the tissues. These abscesses may, therefore, be regarded as essentially analogous to the ulceration of the intestines in typhoid fever and the sore-throat of scarlatina.

As the third stage of the fever gradually progresses, the glands slowly regain their proper functions; the paralysis which in fevers *recovered from* has been only temporary disappears, and the patient slowly returns to health.

We thus have the analogies between fevers and inflammation complete, temporary eccentric paralysis (congestion) having its analogue centrically in fever recoverable from, and permanent eccentric paralysis (inflammation) being analogous to fevers which prove fatal. Having thus treated at length the first class of facts, the phenomena common to all fevers, we will now consider shortly the second part of this subject.

2. *The Special Phenomena.*—And here the first thing that strikes us is the remarkable symptoms which different fevers present when they show themselves externally, and the different forms which the eruption assumes when present. Thus, in *measles* "the eruption consists of papulæ gradually coalescing into blotches, often horseshoe-shaped and slightly raised above the skin. They are of a dingy red colour, and come out on the fourth day." The period of incubation here is from ten to fourteen days. The mucous membrane of the conjunctivæ, Schneiderian membrane, fauces, larynx, trachea, and bronchi are the parts secondarily affected. "In *scarlet fever* the eruption is an efflorescence of the skin, mucous membrane, and tonsils." It appears about the second day, and declines after the fifth. The parts secondarily affected in scarlatina are the throat and kidneys. In like manner we might go over almost all fevers, but must content ourselves with stating that this difference in these phenomena and symptoms appears to depend—first, on the nature of the hypothetical poisons; and secondly, on the different structures of the skin, upon which, from their inherent properties, these poisons are predisposed to act.

Of all the fevers, however, which could be considered, the *intermittents* are those which show most distinctly their connection and relation with disease of the sympathetic system; for, in addition to the ordinary phenomena of fever, we have the peculiar intermissions and remissions. These have evidently their analogues in the healthy action of the circulatory, digestive, and genito-urinary systems; and as in those cases we have shown that the periodicity of their action was in all probability due to the regulating function of the white fibres, so in intermittent fever, in addition to paralysis of the sympathetic, we have in all probability the cerebro-spinal system to a greater or less extent involved. So little light, however, has as yet been thrown on the functions of the brain, that we cannot even hint at the portion affected.

Having thus shown that inflammation and fever are in reality nervous diseases, it will readily be seen that we only want the cerebro-spinal affections to form a complete epitome of pathology. From this an important deduction can be drawn, and one to which all the facts of scientific pathology appear at present to point; namely, *that all diseases may be considered as due to derangement of the nervous systems.*

Dundee Royal Asylum,
Nov. 8, 1860.

ON THE FREQUENCY OF MORBID ALTERATIONS OF THE UTERINE APPENADGES IN CASES SAID TO BE UTERINE.

(From the 'Gazette des Hôpitaux.')

Of the various organic systems, there are few that, for a certain number of years, have been the subject of so much clinical study and research as the uterine system. From this concourse of inquiries there has resulted more contrariety than unanimity of opinion regarding the principal points in the pathological history of the uterus and its appendages. As a proof, witness the discrepancies which at this moment exist among those who have given most attention to this subject, as regards both the origin and actual seat of the tumours and phlegmonous congestions that occur in the vicinity of the uterus. Nor are these discrepancies without utility; for they teach us to receive with distrust every exclusive theory, and lead to new studies before forming a definite judgment. Such new facts and particular views as could serve to elucidate this question should all be received with the same degree of favour. For this reason, independently of the merits of his work, we intend here noticing some of the views which Dr Siredey has very ably developed, in the thesis which he recently defended before the Parisian Faculty of Medicine, on the part which the uterine appendages enact in affections said to be uterine.

During my sojourn in the hospitals, says Dr Siredey, I had opportunities of seeing a very considerable number of women affected with uterine disease; and I was always struck with the length of time they were under treatment, the slowness of their convalescence, the readiness with which relapses occurred, and the small number of real cures. Yet the patients were submitted to the most scrupulous examination, and nothing was neglected that could have any bearing on the local or general state. The most judicious attentions were lavished on the patients, who, ere long, experienced much improvement; the general state became better, the neck of the uterus less voluminous, the ulceration which covered its orifice cicatrised, and the vaginal discharge had either become less abundant or had nearly ceased; while the pains affecting the loins, the hypogastrium, and thighs had disappeared, when the patient, now wishing to return to her usual avocations, left the hospital *cured*. Yet, when in such cases a close examination is made, you fail not to discover such signs as must lead you to a degree of reserve in your prognosis. Notwithstanding the great improvement that has taken place, there still remains some degree of firmness in the cervix uteri; and in the lateral parts you still find a sensible degree of resistance, which fail not to become the source of new symptoms as soon as a spark alights on the site of the former conflagration. "This," says Dr Siredey, "is what we have a hundred times witnessed, and such is the result of these cases." After a delay of some weeks, months, or even years, from the fatigue of another accouchement or abortion, or even from the menstrual flux or other cause of uterine excitement, the same patient returns again to solicit a bed in the hospital. This time the general health is more sensibly affected; the countenance has an expression of suffering; the emaciation has increased; the pains are more acute and more persistent, and extend to the hypogastrium. A new examination is made, when, besides symptoms of phthisis pulmonalis and chloroanæmia, almost always met with, we discover acute inflammation of the vulva; the vagina bathed with a mucous secretion; the neck of the uterus ulcerated, or not ulcerated, but painful and nearly immovable from adhesions to the pelvic parietes; a resistance more or less profound and of greater or less extent in the *culs-de-sac* of the vagina, or a doughiness or tumefaction over the sides of the uterus; in a word, we see that assemblage of symptoms or that morbid state which has been designated by the name of peri-uterine phlegmon, or peri-metritis. The seat of the principal morbid phenomena in such cases is no longer the uterus, but its appendages. As M. Negrier has proposed an exchange of terms, and would consider the ovary and tube as the essential organs, and the uterus as their appendage; so, in pathology, M. Siredey considers the affections of the uterus as subordinate to those of the ovary, the tube, and their common membrane the peritoneum. "The diseases of these organs, therefore, take the lead in the entire uterine pathology; the hidden depth of their situation, and the difficulty with which they are reached, give rise to the uncertainty that attends their diagnosis; while, on their connection with the great abdominal serous membrane, so ready to take on an inflammatory action, their gravity depends." Such is the idea that forms the subject of M. Siredey's thesis; but we shall not follow the physiological and anatomical reasons which he adduces in support of his proposition, but shall restrict ourselves to an exposition of some of the clinical facts which he believes give to his views the sanction of experience.

Among the most frequent causes of peri-uterine inflammation, abortion and labour hold the first rank. According to M. Aran, to these causes are attributable 62 cases in

every 100. Our readers will recall the terrible epidemic from which puerperal women suffered in 1859, on which occasion the subject of puerperal fever was brought before the Academy of Medicine by M. Guérard. M. Siredey was at that time an interne of the Lariboisière Hospital, and had, therefore, opportunities for collecting valuable materials for the illustration of this subject: and these we shall here condense. From the 1st of January to the 1st of July, 382 women were admitted, and of these 72 had recently been confined. Of this last number, 34 left the hospital cured or convalescent: all of them had shown, in various degrees, well-marked symptoms of metro-peritonitis. In 22 of the remaining 38 cases, the tubes were found dilated and filled with pus; the ovaries voluminous, softened, and purulent. While taking into account the epidemic influence to which must be referred much of the frequency and extent of these lesions, it must yet be evident from these statistics how important is the share to be attributed in the lesions to parturition. If these 22 cases be viewed in connection with the 34 who left the hospital cured or convalescent, and who all presented, in various degrees, the same morbid phenomena,—acute pain in the iliac fossa, fulness, and sometimes real tumefaction deep in the same region,—M. Siredey considers that there is reason for admitting, at least in the majority of the cases, if not in all, that these symptoms have been produced by inflammation of the ovary, which has in turn given rise to circumscribed pelvi-peritonitis. To the objection that might be made, and which he has himself anticipated, that the intra-pelvic tumefaction might have had its seat in the broad ligaments, he replies that in the autopsies which he made, he did not see so much as one instance where pus had collected in the broad ligaments in such a way as to be conspicuous.

But it is not puerperal ovaritis alone which, according to M. Siredey, may be the source of peri-metritis. Of the lesions that have their seat in the ovary, there is one on which he especially insists as capable of giving rise to this affection: and that is tuberculisation; of which he gives two striking examples, which occurred to M. Aran in the course of last year at the Hospital St Antoine. They were two fatal cases of tubercular peritonitis; one following tuberculisation of the tubes; the other, chronic tubercular ovaritis followed by peritonitis.

We shall add a few words on the principal anatomical alterations of the uterine appendages observed by M. Siredey in the numerous autopsies which he made, and afterwards notice the practical consequences that may be deduced from them.

The ovaries and tubes, says M. Siredey, are usually simultaneously affected with inflammation; and it is unusual to find the tube sound when the corresponding ovary is diseased, or the ovary sound when the tube is affected. Inflammation of the ovary may be acute or chronic. In the former case, the ovaritis is generally simple, and occurs usually in the left ovary; in the latter case it is double. In the acute form, it is quickly attacked with inflammation. Sometimes the pus has its source in inflammation of one or more follicles; in other cases it proceeds from the whole organ generally. M. Siredey saw a case of this kind in a woman who recently succumbed to an attack of tubercular pleurisy. In the chronic form, which is most frequent, the lesions are no longer the same. Pus is rarely seen. The ovary, at first hypertrophied, is at a later period converted into a shapeless mass, the seat of numerous alterations—cysts, tubercles, various morbid productions, &c. One of the most curious points in the pathological anatomy of inflammation of the ovary, pointed out by M. Siredey, is the position which this organ assumes. At first, owing to the hypertrophy which it undergoes, it falls, by its own weight, to the bottom of the pelvic cavity; adhesions next take place, by which the organ becomes fixed in this situation. The consequences of this must be obvious in their bearings on the symptomatology and diagnosis of the affections under consideration. The tubes, generally increased in volume in acute cases, are embossed and undulating, and reverted on themselves; the fimbriæ of the pavilion are considerably hypertrophied, are fungiform in appearance, and sink from their weight towards the lower part of the pelvis when not prevented by existing adhesions. In a case seen this present year by M. Siredey at the Hospital St Antoine, in a woman who, during life, had a voluminous retro-uterine tumour, and who died after manifesting at the onset symptoms of pelvi-peritonitis, the fimbriæ of the pavilion were found hypertrophied, adhering together and forming a tumour the size of a hen's egg. The walls of the tubes generally were found thickened, and the degree of their hypertrophy corresponded with that of the ovary. Their mucous membrane, almost always the seat of well-marked vascularity, is usually immersed in a turbid, puriform fluid. Lastly, in this situation was found, more frequently than in the ovary, tubercular matter in different degrees of softening. Another order of lesions is pointed out by M. Siredey as influencing a great number of morbid alterations of the uterus and its appendages: we allude to circumscribed pelvic peritonitis, which sometimes terminates in a cyst in the midst of false membranes, the result of inflammation, agglomerating all the parts together; sometimes in an abscess which not unfrequently opens into an adhering part of the intestine. According to our *confrère*, who fully shares the views of Bernutz and Goupil in their memoir of 1857, it is this circumscribed, encysted pelvic peritonitis which has hitherto been generally considered as phlegmonous congestion of the peri-uterine cellular tissue.

The practical consequences resulting from these facts we shall reserve for a future number.

THE SPIRIT OF THE PERIODICALS.

The 'Medical Times and Gazette' opens with a continuation of Dr Goodfellow's Lectures on *Diseases of the Kidney*. In his present lecture he treats of the influence of alcoholic compounds in inducing those diseases, and explains his views of their mode of action. He makes the following interesting remarks upon

"*Their Physiological Action.*—According to current notions, which are founded for the most part upon the theory of Liebig, supported by the experiments and researches of Bonchardat and Sandras, and since also by Duchek, the alcohol passes in the system, principally in the blood, through several oxydising stages, until it ultimately becomes metamorphosed into carbonic acid and water, which are exhaled principally by the lungs. This theory, so plausible, and so satisfactory in many respects, and so calculated to explain many acknowledged effects of alcohol, and supported as it is by the results of direct experiments and chemical analyses made by the first chemists of the day, was generally received as true. According to this theory, alcohol was regarded as an aliment—one of the tertiary, non-azotised aliments,—and therefore subserving the processes of respiration and calorification. The successive changes that alcohol was supposed to undergo in the capillary vessels of the system from the oxygen brought by the blood, were into aldehyde, acetic acid, and carbonic acid and water. The carbonic acid resulting from the decomposition of the acetic acid was supposed partly and chiefly to get out of the system in a gaseous state by the lungs, partly to become united to several bases, and eliminated by the kidneys and other emunctories. Duchek goes so far as to say that it sometimes becomes converted into oxalic acid. It has been generally observed that the quantity of carbonic acid in the air expired soon after the ingestion of alcohol or any spiritnous liqnors is very perceptibly diminished, and considerably less than before. To explain this diminution, it has been stated that alcohol, by the action of an oxydising body, loses two equivalents of hydrogen, and gives rise to aldehyde:—

$$C_4\,H_6\,O_2 \div O_2 = 2\,H\,O + \underbrace{C_4\,H_4\,O_2}_{\text{Aldehyde.}}$$

At a second degree of oxydation, the alcohol loses two equivalents of hydrogen, which are replaced by two equivalents of oxygen, and acetic acid is produced:

$$C_4\,H_6\,O_2 \div O_4 = 2\,H\,O + \underbrace{C_4\,H_3\,O_3,\,H\,O}_{\text{Acetic Acid.}}$$

"This transformation of alcohol into acetic acid takes place out of the body, as you know, under the influence of ferments, or dry platinum-black. By a further oxydation the acetic acid becomes converted into carbonic acid and water, which are ultimately carried out of the system in the way I have already pointed out.

"Nothing apparently could be more satisfactory than this explanation, and you perceive how completely it accounts for the diminution of the quantity of carbonic acid. The alcohol takes all the oxygen, and, therefore, the fatty matters cannot be burnt off; they remain in the system to give rise to the drunkard's fatness, whether deposited as fat, or taking the place of the proper organic principles, and leading to fatty degeneration. The whole of the oxygen is used up in gradually converting the alcohol into carbonic acid, which, as it is slowly evolved, unites with the different alkaline and earthy bases, to be finally eliminated by the kidneys and liver. This was supposed very likely to happen when, from the deadening, numbning, paralysing influence of the alcohol upon the nervous and muscular systems, the respiratory movements became so reduced in frequency and extent, that but little oxygen could be introduced into the blood, from the small quantity of air gaining admission into the lungs.

"Now all this theory, plausible and satisfactory as it is, has been completely, and, I think, successfully, proved to be false. It will not bear a searching inquiry into the true facts of the case. And after all, as the sequel will prove, we are obliged to come back to the old opinions, as derived from unbiassed experiments, and before facts were made to square with chemical theories. MM. Lallemand, Perrin, and Duroy have made this inquiry in the true spirit of philosophy, and in the most searching manner. It is impossible to read the account of their experiments and analyses without being convinced that they had one object alone in view, and that was truth, apart from any preconceived views or theories. It is altogether out of the scope of these lectures to quote at length the beautiful, ingenious, and very satisfactory experiments by which they have been led irresistibly to their conclusions. Suffice it to say that the results of their experiments admitted of no other conclusions than those which the authors came to, and which are of great value in explaining the pathogenic action of alcoholic and allied substances. These gentlemen, then, have found upon evidence, which I do not see how any one can gainsay, that whether alcohol, or its compounds, brandy, rum, gin, or whisky, be taken into the stomach, or inhaled by the lungs, it is only found as alcohol in the blood and in the tissues, especially in the nervous substance, for which it would seem to have a special attraction; and that it has no claim to be regarded as an aliment. When taken into the stomach, some small portion may be converted into acetic acid, by the gastric juice and the mucus acting as ferments. But even this small quantity does not enter the blood. In this list fermented drinks which contain more or less nutrient matter mixed with the alcohol must be excluded, such as wine, beer, cider, perry, &c. Wines contain even nitrogenous matters, also colouring and fatty matters, and salts; cider contains glucose, mucilage, vegetable acids, &c.; beer also contains glucose, dextrine, and allied substances in considerable proportions, nitrogeneous matters, bitter and aromatic principles, and salts. According, then, to MM.

Lallemand, Perrin, and Duroy, alcohol is neither transformed nor destroyed in the organism, and is ultimately eliminated without undergoing any modification. They have detected it in considerable quantity in the blood, brain-substance when freed from membranes and blood, and in the urine by means of distillation; they have shown afterwards, by the aid of exact doses analogous to the process of analysis by the method of volumes, that alcohol diffuses itself in the tissues, and that it accumulates in the brain, and in the liver, where it is found in larger quantities than in the blood and other organs. They have proved by multiplied experiments, verified by counter-proofs, that alcohol does not undergo any modification in the economy, and that it does not give rise, consequently, to any bodies resulting from its oxydation, such as aldehyde, acetic acid, &c. It is only in the stomach that it is susceptible of experiencing any modification, for a small fraction of alcohol ingested is there converted into acetic acid by the action of the gastric juice and the mucus, which act then as a ferment; but this action, altogether local and special to the stomach, ceases the moment the alcohol penetrates the venous radicles. These authors have shown, moreover, that it is eliminated by the lungs, the skin, and the kidneys, as alcohol. It is not only after the ingestion of a *great* quantity of alcohol that they met with it in the organs, for they found it in the blood of a dog, nine hours after he had taken only 30 grammes (3 drachms 37½ grains) at 21°; they met with it in a man who had drunk about 30 grammes (about 3½ drachms) of brandy; they observed, finally, that the pulmonary exhalation of a man who had taken a litre (⅞ths of an Imperial quart) of wine, of a middling alcoholic richness, contained alcohol for eight hours after taking it, and that the urinary secretion gave evidence of its presence during fourteen hours. The authors may well ask,—'Is this the mode of action of an aliment?' All the tests for the detection of aldehyde, and acetic acid, were had recourse to after alcohol had been administered in various ways, and in every dose, but without avail; whereas when very small quantities of these substances were administered, evident indications of their presence in the blood, and in the organs, and in the exhalations from the lungs, were at once observed. I have already described how the diminished quantity of carbonic acid exhaled after the ingestion of alcohol was explained under the old theory. It remains to show how the diminution can be accounted for under these observed, indisputable facts. Now, it appears, from the researches of MM. Lallemand, Perrin, and Duroy, that alcoholic substances exert a very remarkable action upon the blood, which presents in animals alcoholised numerous globules of fat, like cholesterine, visible to the naked eye, and swimming on the surface of that fluid. This is of such interest in connection with our subject, that I shall again refer to it when I come to speak of the pathological effects of alcohol. At present it is in its physiological aspect that they are of importance. Since alcohol produces a modification so singular, may it not offer also, when present, an obstacle to the disengagement of carbonic acid, or delay even the combination of oxygen with the carbon of the blood? If this be the case, alcohol contributes to nutrition, not actively as an alimentary substance, but in an indirect manner in exercising a moderating influence upon organic decomposition. With respect to its influence independently of this separation of the fatty principles, and perhaps their conversion into a non-saponifiable state, but little is positively known. It is conceivable, however, from the properties which alcohol is known to possess,—its great diffusiveness through, and attraction for, water,—its power of dissolving some very important animal principles, and of coagulating others,—that it does exert a considerable influence upon the physical, and also probably upon the chemical qualities of the blood, and blood-corpuscles. Nothing definite, however, has been observed. Dr Addison, of Brighton, whose able researches have thrown light upon some physiological and pathological processes, has observed some very curious effects upon adding sherry wine to blood out of the body; and it is possible that alcohol, when taken into the system in large quantities, may in time work such changes, and even destroy the red corpuscles already formed, and hinder the full development of others. MM. Lallemand, Perrin, and Duroy, however, saw no alteration in the corpuscles, even when alcohol was added to the blood out of the body, and also in blood taken after large quantities had been imbibed."

(To be continued.)

Dr Richard P. Cotton continues, in the same journal, his observations on the *Action of Certain Substances upon Phthisis*. Dilute hydrochloric acid is the remedy reported on in this article. The dose was from ten to fifteen minims. Dr Cotton says:

"Of the twenty-five patients, eleven greatly improved; six slightly improved; and eight received no benefit. Of the greatly-improved cases, seven were in the first, two were in the second, and two in the third stage. Of the slightly-improved patients, one was in the first, one in the second, and four in the third stage. Of those who received no benefit, two were in the first, one in the second, and five in the third stage.

"Sixteen patients gained in weight; eight lost weight; and in one there was no alteration. The changes in weight were particularly noticed in reference to the cod-liver oil. In six cases, although no oil was taken, there was a great increase of weight (an average of six pounds to each patient); but in all the rest who either did or could not take the oil, there was more or less loss of weight. Without reference to the oil, however, those greatly improved were found to have increased in weight, although such increase bore no direct proportion to the amount of improvement, some who had gained the least having been quite as much benefited as any of the rest.

"The improvement was in several cases very marked indeed, both locally and generally; the disease appearing to be arrested, and the patients declaring themselves 'quite well.' This was especially noticed in three cases, in one of which the disease was already in the second stage; in two of these no cod-liver oil had been taken, in one this remedy had been occasionally added to the acid. Two other persons, who had actual vomicæ, also improved very decidedly, the pulmonary secretion greatly diminishing, all the general symptoms subsiding, and the patients ultimately leaving the hospital materially improved in every particular. Of the seventeen more or less improved cases, seven took no oil; while in ten, it was occasionally taken in combination with the acid: in two of the latter cases the oil seemed to make little, if any, difference; but in at least four, it appeared to contribute materially to the general result.

"In five of the patients who were obviously benefiting under the hydrochloric acid, the experiment was made of changing it temporarily for an equivalent dose of *liquor potassæ*. In one of these there was no marked effect, the patient appearing to do equally well under either acid or alkali; but in the other four the change was more or less prejudicial, the patients unhesitatingly affirming that they were progressing less than when taking the acid. Much care was used when making this observation, the patient's own words being, in each case, recorded.

"In very few instances did the hydrochloric acid at all disagree. Now and then a little gastric pain was complained of, but in no case was it necessary permanently to abandon its use. As a general rule, the appetite greatly improved under its administration.

"For some years past I have frequently prescribed for phthisical patients the mineral acids in conjunction with gentian and other vegetable tonics; but I became anxious to examine, as far as possible, the separate influence of the acids. The frequency with which consumptive persons suffer from dyspepsia—the fact that the free acid frequently occurring during healthy digestion is the hydrochloric—together with the well-known solvent effect of this acid upon the plastic constituents of the food, pointed rather to it as the proper object of the experiment, than to either the nitric or sulphuric acid. I have no reason, however, to think that either of these acids, or the compound known as the nitro-hydrochloric acid, may not be equally beneficial; but upon this point I hope to make further observations.

"After making due allowance for other influences, so favourably brought into operation at the Consumption Hospital, I cannot help coming to the following conclusions:

"1. That the mineral acids are well suited to a large number of phthisical cases.

"2. That the dilute hydrochloric acid especially, in doses of ten or fifteen minims twice or thrice a day, is an important auxiliary to other treatment; and may oftentimes be usefully employed, either alone, or in conjunction with other mineral or vegetable tonics."

Mr Henry Smith contributes an article on some points connected with the *Pathology and Treatment of Prolapse of the Rectum*, and Dr Hobson continues his papers on *Medicine in China*. We quote the annexed paragraphs on the pulse:

"As the pulse plays such an important part in diagnosing and prognosticating disease in China, I ought, before going farther, to describe in a few words the Chinese theory of the pulse, on the right knowledge of which, the Chinese say, all treatment of disease depends. It is the foundation upon which the whole superstructure of their Medical practice rests. Demolish this, and institute in its place the true knowledge of the circulation of the blood, and the first step is made for future improvement. Some able foreign writers upon the Chinese have affirmed that they do understand the circulation of the blood; which, they say, they find given in Medical treatises on the pulse. I doubt the competency of any one, but a Medical man conversant with their writings, to say whether the Chinese have a knowledge of the circulation or not. I acknowledge they knew ages ago that the blood is the chief source of life, and that it moves or oscillates in blood-vessels; but the anatomy and proper function of the heart is unknown: there is no special name of, or distinction between, arteries and veins, still less of the intermediate vessels, the capillaries; there is no mention of the valves of the veins, which struck Harvey so forcibly as being put there for some object; no allusion to the change of blood in the lungs, nor anything, in fact, said about its circulating in a double circle; nor its special uses in the economy. The same words, also, which are used for the motion of the blood, are equally applied to the circulation of the spirits, or air: which moves about in vessels, as well as the blood, and which is no new theory; for arteries, being always found empty, were supposed to contain air by Hippocrates, and even down to a much later date. But the Chinese theory of the circulation and the pulse is not only absurd, but impossible; its untruth is proved to demonstration on the very face of it; for it sets at defiance the simplest laws of hydraulics, and gives a vital force and quality to a pulsating and conducting tube, which it could never possess. The extent of the pulse is one Chinese inch on the right and left wrists, and nowhere else. It is divided into three parts, called Tsün, Kwan, and Chih: each of these has an external and an internal pulse; that is, there is a distinct pulse in each of these three places, and on the inner and outer side of the pulsating vessels, making altogether twelve pulses, six on the right and six on the left. This explains why both wrists must be felt, and the astonishment that is expressed on a foreign physician's being content with feeling the pulse in one wrist only. Besides these twelve, there are others which scarcely admit of explanation, being too refined even for Chinese Doctors themselves, and are confessed to be unimportant in practice. But of those just mentioned, each one of the twelve corresponds with, or belongs to, twelve viscera, two of which are imaginary—viz., the gate of life, and three upper, middle, and lower membranous expansions, which I translate membranes of the viscera. The following table will show the theory more clearly:

"Chinese Theory of the Pulse.

"*Extent.*—One inch, or three fingers placed side by side on the right or left wrist.

"*Division.*—Into three parts.

"1st, called Tsün; 2nd, Kwan; 3rd, Chih.

"Pulse of the Left Wrist.—Tsün—External side belongs to the heart; internal side, to the small intestines. Kwan—External side, to the liver; internal side, to the gall-bladder. Chih—External side, to the kidney; internal side, to the bladder.

"Pulse of the Right Wrist.—Tsün—Outside, belongs to the lungs; inside, to the great intestines. Kwan—Outside, to the spleen; inside,

to the stomach. Chih—Outside, to the gate of life; inside, to the membranes of the viscera.

"There are four kinds of pulse. 1st, *Fow*, the strong, full pulse. 2nd, *Chin*, deep, feeble, small pulse. 3rd, *Che*, the slow pulse. 4th, *So*, the quick pulse.

"The three places of the inch pulse may each have a different pulse.

"The Kwan may be *Fow*, or strong and full; the Tsün may be *So*, or quick; the Chih may be *Chin*, or small and feeble—all at the same time.

"Who can say, with this theory before them, that the Chinese know anything about the true circulation of the blood! Its glorious discovery is alone due to our celebrated countryman, Dr Harvey, in the time of Charles. But the Chinese are not only ignorant of the circulation, but of the cause of the pulse; the propelling power of the heart, and the conducting power of the arteries, are altogether unknown. There is no pulse for that important organ the brain, or the spinal marrow, muscles, and bones, &c. But while they write learnedly about the wonderful properties of the pulse, and palm a lie upon the public, in professing to distinguish its minute and varied forms, yet I have never met with one Chinese Medical Practitioner who dared affirm to my face that he had done so; or was willing to try his boasted skill upon any patient of mine, though offered a considerable reward, to point out any well-known disease by the pulse alone. The doctrine of the circulation of the blood being so important, I entered upon it very freely in a Treatise on Physiology, and I rather expected, as it ran counter to their views, and, if received, would in time prove fatal to their darling and much-vaunted theory, that it would meet with opposition and ridicule. But, singular enough, it was generally admitted to be true, or at least unobjected to and unopposed in any way; but it may be long before these new views will shake the public confidence in a long-trusted oracle."

Mr Hilton's Lectures on *Pain* are continued in the 'Lancet.' The Author reports several instances in which *rest* cured old sinuses and ulcers, the *methodus medendi* being simply to control muscular action. We extract some of the cases:

"*Sub-occipital Abscesses.*—Abscesses under the occipito-frontalis muscle are sometimes very large, and resist surgical treatment for a very long period. Why is this? Let me remind you that the areolar tissue in which this abscess exists is abundant, and that the whole superficies or dome of the abscess is under the influence of the occipito-frontalis muscle. Hence there is no rest to the abscess; it never has a chance of quietude, or of accurate and persistent coaptation of its surfaces, from the disturbance produced by the movements of this muscle. That such abscesses are difficult to heal will be admitted when I mention the particulars of some cases; and I will endeavour to demonstrate to you that in the surgical treatment of such cases the great object should be to keep the occipito-frontalis perfectly quiet. I would say, then, that chronic abscesses or sinuses under the scalp may be cured by keeping the occipito-frontalis quiet and at rest, by strapping.

"In illustration, I may mention this case to you. Last spring I was requested to see a stout gentleman, aged fifty, who had fallen down the hold of a ship. He had been taken to the London Hospital, where his wound was well dressed. The anterior half of the scalp was injured; it had been turned forwards and downwards, quite over his face, by the accident. This flap was replaced in accurate position, bandaged and strapped, and the patient was sent home. Not any primary adhesion took place in the wound, and in a few days his surgeon thought it right to take off the dressing, when it was found that the scalp itself was much swollen, and that the whole of it was lifted up or raised from the bones by sub-occipital suppuration. The patient subsequently had two attacks of severe hæmorrhage, from sloughing and ulceration of the temporal arteries, which required ligatures; and it is worthy of remark that the bones of the cranium were denuded of pericranium to the extent of several inches, and were daily exposed in this condition during nearly a fortnight. Yet the bones did not die, their nutrition being derived from the blood supplied by the arteries of the dura mater. The wound was dressed daily with lint and warm water, and the pus squeezed out from under the whole of the occipito-frontalis; but the abscess would not heal, and the question was, how to get the pus from under the posterior part of the scalp—for there was no outlet for it in that direction—and how to secure rest to the movable dome of the abscess. The hair upon his scalp was shaved off, and long strips of plaster were so arranged across and around the head as to empty the abscess, to keep the occipito-frontalis quiet, and to press it downwards upon the pericranium and bones: this was done simply for the purpose of giving rest to the parts. The rapidity with which the abscess then healed was very remarkably in contrast with the tardy results of previous daily dressing and emptying the abscess. He quickly got well, and without any necrosis of bone."

"*Deep Cervical Abscess, followed by a Sinus.*—I have here the notes of another case, where a sinus existed in the neck, and was cured by rest. This case was of two years' duration, and was cured in three weeks by rest. I am almost afraid you may be induced to fancy I am using the language of exaggeration in this statement; but really it is not so.

"In 1849, Elizabeth H——, aged twenty, living at Lambeth, had had a large abscess extending deeply under the platysma myoides and the sterno-cleido-mastoideus. This had continued as a long sinus, discharging freely during many months. She had been an hospital out-patient during two years. Iodine, &c., had been injected into the sinus, and a seton passed through it, and retained within it for some time without any benefit. Strips of adhesive plaster were drawn tightly over and across the muscles covering the sinus, and the head was steadied by a pasteboard splint, cut rudely into a form which could be adapted to the pelvis, along the back of the shoulders to the back of the head, and then laterally on each side, so as to embrace the whole of the head in a circle of pasteboard. A figure of 8 bandage was then applied over this apparatus around the head and under the axilla, crossing in front of the chest, so as to fix the head and neck forward and a little downwards firmly upon the shoulders, and to relax the muscles. The sinus ceased to discharge at the end of a fortnight; but she continued to wear the apparatus for a short time—about three or four weeks—longer, as a further security.

"This patient was thus cured by rest."

"*Cases of Carbuncle, followed by Sloughing.*—We all know that it is not easy to manage successfully the treatment of a patient who has had a large carbuncle on the back of the neck near the scalp, which, by destroying the sub-cutaneous areolar and fascial structures, leaves large portions of loose overlapping skin, blue, dark-coloured, and congested, showing a very feeble power, and, added to this condition, the trapezii muscles exposed to view. Now I wish to show the therapeutical value of local rest in the treatment of such a case.

"Two years ago I saw the wife of a physician whose condition accurately resembled that which I have just delineated. She had been previously attended by a very eminent London surgeon. The case was not proceeding satisfactorily: there was no local evidence of repair; the wound had remained stationary during some time before my visit. On looking at the patient's neck, it appeared to me that there were two additional requisites in the treatment which might help the cure: one was to arrange some simple mechanism which would keep the trapezii muscles quiet; and the other, to support in their proper positions, and to maintain in a state of perfect rest, the loose, feeble flaps of skin. I hoped by such means to facilitate adhesion of the two granulating surfaces. The loose flaps of skin were laid neatly upon the subjacent trapezii, and then a large, thick pad of cotton wool was firmly fixed upon the surface of the flaps of skin and surrounding parts. A bandage was applied around the head, and extended as a figure of 8 bandage, crossing behind the neck and under the armpits, in order to fix the head, neck, and shoulders, and control the trapezii. In twenty-four hours the healing commenced, and proceeded, under the same local treatment, to the most satisfactory and speedy termination.

"Not long after that time, I saw a patient with Mr Wright in the Clapham road, where precisely the same circumstances occurred, with precisely the same treatment, and precisely the same result. Here the parts were kept at rest partly by a thick pad of cotton wool pressing upon the flaps, and by means of a bandage to keep the head and the trapezii muscles in a state of rest. Cases of the same kind, with the same result from the same treatment, have occurred to me lately in Guy's Hospital.

"*Popliteal Abscess and Sinuses.*—Sinuses in the popliteal region, in unhealthy subjects, are very difficult to cure, except by local rest; and here I will take the liberty of reading part of a note which I received from a surgeon in Essex, who had sinuses at the back of his knee-joint:—

"'Jan. 9th, 1853.—My sinuses occurred after an abscess in the popliteal space, which left a very irritable, unhealthy ulcer, the size of a walnut, and several long and deep sinuses extending from it, amongst the tendons of the hamstring muscles. Not being able myself to improve this ulcer, I consulted the late Sir A. Cooper, who stated that it was owing to a defective state of my general health, and ordered me steel and quinine, to inject nitric acid lotion, to take exercise, and to wear a high-heeled shoe. At the end of many weeks, the ulcer and sinuses remained as they were. You then saw me, and ordered my leg to be flexed, and placed upon a resting splint upon a wooden leg, and moderate pressure upon the sinuses with soap plaster. I continued this plan, and in two months I was quite well, and have been so ever since, and am in active occupation in my practice.'"

"*Painful Granulations following Injury.*—Some long time after the occurrence of this case, I had a patient in Guy's Hospital suffering greatly from an ulcer at the end of the finger, in which it was supposed there was a piece of broken glass, as the original injury was a cut from breaking a window. She had been under the observation of a surgeon, who had tried repeatedly to get out the supposed piece of glass, and had punished her severely, but unintentionally. She came into the hospital, and I thought the case would give me a good opportunity of making a demonstration of what I had long deemed to be correct, and taught. On placing the broad end of my own finger upon the ulcer, it gave her exquisite pain; the broad surface of my finger, however, was not a sufficiently accurate localizer of the pain. I then employed the rounded end of a probe, and with great care examined the whole surface of the ulcer by pressure, until I came upon a spot that was exquisitely tender, and produced dreadful pain to the patient. With a pair of scissors I cut out the painful granulations. Explaining to Dr Habershon, the Demonstrator of Anatomy at Guy's Hospital, the views I entertained regarding the cause of the painful granulations, I requested him to examine them by the aid of the microscope, and he found in them, and near the surface, as I had expected, looped filaments of nerves, thus completing the demonstration of the cause of the pain. From the time of my cutting away those sensitive granulations the pain ceased, and the sore began to heal: there was no more trouble or difficulty as regards the treatment of the ulcer; it got well by giving it '*physiological rest.*'

"*Exquisitely painful Ulcer after Injury.*—About a year and a half ago, I was requested to see a gentleman's coachman, who, on getting off his box seat, slipped his fingers between the lower bar and his seat, and thus had two of his fingers broken off at the second phalanges. One of them went on rapidly towards healing, and healed very well. The other remained swollen, irritable, very painful to the touch or on exposure to the air, preventing sleep, and producing great constitutional disturbance. We failed to relieve these symptoms by the local and internal employment of opium. This unhealthy condition could not be from any constitutional defect, because one finger did well; nor could it be from the result of any dissimilarity of the original injury, for they were precisely alike. With the surgeon in attendance, I made a careful examination of the part; and when I placed the end of a probe towards the edge of the ulcer upon the finger, it detected a spot which was exquisitely tender, and the patient screamed out—'Oh, pray, for God's sake, cover it over! I can't stand it.' The position of this pain was in the course of one of the lacerated digital nerves. I passed a pointed bistoury under the nerve, about one-fourth of an inch above its exposed portion upon the wound, and so divided the nerve. The pain in the ulcer immediately ceased, and the touch of the probe caused no un-

easiness. From that time all the local symptoms rapidly improved, and the case gave no further trouble, being quickly cured by 'physiological rest.'

"These cases prove distinctly that an ulcer may be very much modified in its character from the exposure of a nerve in the wound.

"I mentioned this subject to my colleague, Mr Cock, some time ago, and shortly afterwards he had an opportunity of testing the value of the observation. He recognised the condition of such an ulcer as that I have referred to, and divided the exposed nerve; the patient lost the pain, and the ulcer quickly assumed a healthy character and got well.

"*Painful irritable Ulcer of the Leg.*—I have here short notes of two other cases that have occurred lately, under my care, at Guy's Hospital, to which I will, with your permission, now allude.

"John J——, aged twenty-seven, sailor; admitted on the 9th of November, 1859, suffering from syphilitic sore on frænum and penis, with secondary eruption and a very painful ulcer on the inner malleolus of his left leg. The syphilis was treated and cured by Plummer's pill, five grains, twice a day; but the painful ulcer remained uninfluenced by the mercury.

"This is the history of the ulcer, provided by my dresser:—

"'When leaping, about four years ago, he sprained his ancle, and an ulcer formed on the inner malleolus of the left leg. It had made frequent efforts at healing, but never cicatrised completely. It now looked irritable, with no inclination to heal, and was very painful, with intense nervous sensibility localised at its upper margin, which was ascertained by examining it with a probe.

"'Jan. 24th, 1860.—Mr Hilton passed a pointed bistoury a little distance above the tender spot under, and then through, the granulations, thereby severing the filaments of the nerves supplying the morbidly sensitive granulations; and although the patient made much ado about the operation, yet he immediately acknowledged himself relieved by it. The ulcer readily assumed a healing aspect, sensation over the other parts of the ulcer was not more acute than normal, the surface became covered by healthy purulent exudation, cicatrisation daily advanced, and the ulcer was closed in a fortnight, and remained so until he left the hospital, on the 8th of March, 1860.'

"This was a case of irritable ulcer, cured by division of the nerve.

"The other case may be put before you in a few words:—

"Jan. 11th, 1860.—The painful spot of an old irritable ulcer was examined by a probe; the nerve supplying the tender granulations was divided; marked relief was the immediate consequence. This division of the nerve was done on the 11th of January, and on the 16th this is the dresser's report:—

"'The ulcer above mentioned is free from pain, and has assumed a healthy character; its edges are throwing new skin over the granulations. From this time, the painful ulcer required no special attention, and in ten days all was healed.'

"These are cases that appear to me to display very accurately the therapeutic value of what we may fairly term 'physiological rest,' to the abnormal sensibility of the surface of the sore. The division of the nerve had its effect upon the neighbourhood *physiologically*, and the ulcer began to heal.

"I trust I may have thus briefly succeeded in pointing out the true pathological feature of what is termed a 'painful irritable ulcer.'

"And now, Sir, to conclude. I took as my text, 'the influence of Rest in the treatment of disease.' I hope that I may have in these lectures adduced enough to show that the subject was not altogether unworthy of the consideration even of an audience so professionally distinguished as the one I have had the honour of addressing. But the subject increases in interest and importance as it is pursued, and it is, in my opinion, anything but exhausted. Should this remark create in the mind of any gentleman here a different opinion, then I would say to him, Let our difference of opinion be submitted to the influence of 'rest' during the next twelvemonth.

"Gentlemen, I have to thank you for your kind indulgence to the great imperfections of my matter, and to my unstudied style; of these faults no one can be more conscious than myself.

"Mr President, my special gratitude is due to you, Sir, for your daily sanction of these lectures by your daily presence.

"Standing here, Sir, within this great and noble monument to John Hunter, may I venture to think that I have not exposed myself to the imputation of any meretricious or egotistic pretensions? If so, all I can ask of you is, to believe (what I myself feel) that I have only done my duty in trying by my best, yet feeble, efforts to keep this temple sacred to Professional Virtue, Surgical Science, and Truth."

Mr Edwin Canton contributes to the same journal some notes on *Atrophy and Degeneration of the Arteries*, and Dr Wardell a paper on *Enteric Fever*. Mr Baker Brown commences a report, in the same journal, of *Eleven Cases of Vesico-Vaginal Fistula*. We extract the article:

"Case 1.—*Three Fistulæ; several operations; cure.*—(This and the three following cases are abstracted from the reports of the London Surgical Home, taken by the visiting surgeons.)—'S. P——, aged forty-five, married, has had eight children and three miscarriages. Her first five labours were pretty good. Her last labour began at half-past twelve a.m. on Thursday, and lasted till a quarter-past three p.m. on Friday, April 9, 1852. She was finally delivered by instruments. Her urine came away per vaginam immediately after the labour. Six months afterwards she was admitted into St Mary's Hospital, under Mr Baker Brown. On examination, he found two openings, separated by about half an inch from each other, the upper one near the os uteri. He performed several operations upon her without much benefit. Subsequently she entered the Soho-square Hospital, where the actual cautery was frequently applied. On November 1, 1858, she was admitted into the London Surgical Home. On examination, Mr Brown found both the openings much smaller, but the edges very hard, almost cartilaginous. The patient stated that the last doctor under whom she had been, asserted that there were three openings; but at the time, only the two before-mentioned could be seen. Mr Brown operated on these by Bozeman's plan, excepting that the buttons were placed horizontally instead of transversely, as recommended by him. On the tenth day the buttons were removed, and both openings found to be completely closed; but, in a few days, she complained that a very small quantity of urine occasionally escaped; therefore, on December 1, Mr Brown injected the bladder with tepid water, and then found the water escape (guttatim) through another small opening, which was situated at the very apex of the vagina. Around this was a strong band of adhesion, cutting off, as it were, the opening from the rest of the vagina. This was freely divided, and afterwards dressed with oiled lint and sponge tents. On the 3rd of January, 1859, Mr Brown endeavoured to close the opening, which had become much larger, using Bozeman's buttons. Four days afterwards she was taken with violent sickness and diarrhœa; nothing relieved her; and the result was, the sutures were entirely torn out. On the 27th, the patient having perfectly recovered and the parts looking healthy, Mr Brown again operated upon her, and for several days with apparent success; but, on removing the button, there was still a very minute fistula, through which a small quantity of urine escaped, when standing, but not in the recumbent posture. Her health being very much shattered by long confinement, she left the institution for the purpose of going into the country.'

"After this, I lost sight of her till June, 1860, when, hearing that she was quite well, I called on her, and found that such was the case. She stated that she had been gradually getting better, and losing less and less urine, and for the last three months had been perfectly well.

"*Remarks.*—It is evident that the cause of the *last* opening not healing was the unhealthy condition of the vagina, the parts around the opening being almost cartilaginous, and therefore possessing but very slight powers for healing. It will be observed that this case, prior to admission into the London Surgical Home, was one of those treated before the advantages of silver sutures had been proved.

"Case 2.—*Two Fistulæ, the larger one cured by one operation, the second by two.*—N. K——, aged thirty, married; resides at Winchester; admitted into the London Surgical Home on the 20th of December, 1859.

"*History.*—Has had a child, ten months ago; says that she was some hours in labour, the child being very large, but no instruments were used. About nine days after her confinement, she found that she was unable to retain her urine. She then applied to the County Hospital; afterwards she was seen by Mr Buckell, who recommended her to be removed to the Home.

"On examination, two openings were found, one admitting the end of the finger, and the second the end of a No. 10 bougie, with an intervening space not much more than a quarter of an inch. These openings were situated midway between the os uteri and the neck of the bladder.

"Dec. 22nd.—The patient being placed on her back in the lithotomy position, under the influence of chloroform, both openings having been pared, were closed by bar clamps, the larger one requiring three, and the smaller two, iron-wire sutures being used.

"27th.—An escape of urine. On examination, the clamps on the smaller opening had fallen off, because the wires had ulcerated through, but a part of the opening was found to be healed.

"Jan. 1st.—The bar clamps on the larger opening removed, and complete union was found.

"19th.—The smaller opening was again operated upon.

"29th.—Bar clamps removed; complete union was found.

"Feb. 7th.—Discharged quite cured.

"*Remarks.*—It is always difficult to cure two openings by one operation; but it is certain that in this instance the cause of failure was the cutting out of the iron wires; and if silver wires had been used, such would not have been the case. It will, however, be observed, that the cure was effected in five weeks.

"Case 3.—*One Fistula; two operations; cure.*—L. R——, aged forty, married, three children; admitted into the London Surgical Home, April 7th, 1860.

"*History.*—Eleven years ago she was confined of her first child. The labour did not last very long; but as she had previously been suffering from dyspepsia and debility, she became exhausted. The medical attendant thought it necessary to apply forceps, and a fine boy was born, who, however, only lived a few minutes. After the confinement, she was very ill; and, about a week later, she found that her urine dribbled away through the vagina, excoriating the parts dreadfully. Since then she has had two good labours, but has always been in a most wretched condition on account of the constant dribbling.

"On examination, there was found an opening large enough to admit the top of one's thumb midway between the urethra and os uteri, and on the left side of the vagina.

"April 12th.—Mr Baker Brown performed his usual operation, bringing the parts together transversely with five of his bar clamps.

"21st.—Clamps removed. On their removal there was found a *very* small opening, but the rest was healed. Mr Brown was in hopes that this would heal of itself, as there was a healthy purulent discharge; but as it did not do so, on

"May 17th, he again operated in his usual manner, the patient *not* being under the effects of chloroform.

"28th.—Bar clamps removed; no escape of urine.

"June 10th. She left perfectly cured.

"*Remarks.*—When it is considered that this patient had been suffering for eleven years, and, consequently, the parts around were much indurated, and that she was perfectly cured in about six weeks, the result must be considered highly satisfactory.

"Case 4.—*Vesico-Vaginal Fistula; operation; death from pyæmia.*—Mrs W——, aged thirty-four, admitted April 18th, 1860, into the London Surgical Home; mother of five children.

(Continued at Page 346.)

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Untamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B.—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

A Page or Three Columns	5*l.*	5s.	0d.

THE MEDICAL CIRCULAR.

WEDNESDAY, NOVEMBER 21, 1860.

MEDICAL REMUNERATION.

Social life is continually starting new problems, which it is always difficult to solve. Between those who love change, and those who think that the world is very well as it is,—between the aspirants for a higher and more orderly development, and those whose interests in existing arrangements make them insensible to grander aims—between the theorists on the one side, and the practical men on the other,—the quiet and moderate people of whom the bulk of society is composed feel great difficulty in coming to any conclusion upon the questions that are daily pressed upon their attention. Happily, these questions settle themselves in the long-run, if we only give time for consideration and compromise. Every question, in fact, carries its own answer with it as its shadow: but then the shadow is always dark, and many never see it. This shadow, too, has different shapes and elevations, according as light be thrown upon the question from the height of our own intelligence. It is straight enough and well-proportioned to me, but it may be crooked and gibbous to another; and who shall decide between us? It is only by throwing numerous lights upon the question from various points of view that we can rightly interpret it through its shadow—a species of ideal trigonometry to which every social problem must be subjected.

There has been no problem in relation to Medical ethics that has been more discussed than that referring to the proper mode of remunerating Medical Practitioners for their services. The existing practice is manifold, and the various diversities of custom have their abettors. There are those who write prescriptions and receive fees; and among them are some who never take less than a guinea for each visit, whilst there are others who will see a patient two or three or four times for one fee, or even take so small a sum as half-a-crown as an honorarium. Then there is another class of Practitioners who dispense their own medicines, but do not make any charge for them, preferring to make their claim for their attendance; another and a more numerous order claim for their medicines alone, and send in bills at Christmas of very formidable length and full of instructive particulars. Besides these, there is another class of ready-money Practitioners who dispense medicines over the counter, and receive the *quid pro quo* in accordance with the usual trading custom.

Closely connected with the mode of charging is the method of getting patients to charge. Some Practitioners keep open Drug-shops, elaborately furnished with many-coloured carboys, glass cases, gold labels, filtering machines and chemical retorts, and magnificently resplendent with gas, glass, and brass; others have, what is called, a Private Surgery—that is to say, an open outer passage with a door leading direct to an apartment duly provided with mahogany shelves, and an array of bottles and blue jars, with "an alligator stuffed," and a tape-worm in spirits, "to make up a show." There are others who, repudiating—or perhaps cherishing these matters, as it may happen—get up a Medical Club, and do despite to their brother Practitioners by agreeing to attend the honest and independent portion of their poor patients at half-a-crown a year. From the Medical Club we mount to the Dispensary, and from the Dispensary to the Hospital, where practices are picked up in the Out-Patients' Room, and Charity throws her broad cloak over the manœuvre.

There are yet other modes of calling public attention to the superlative merits of the sagacious Practitioner, but the chief of these is by public advertisement. Perhaps this is the most ingenious and artful of all Professional stratagems. One man establishes a dispensary, and advertises that no case is sent away from the doors unrelieved, and affixes his own name as Surgeon at the bottom: this is the puff infamous. Another writes a book and puts his address into the advertisement: this is the puff impudent. A third entrusts his book to Mr Churchill's skill and energy, and with his book his purse also; and he is gratified by a daily publication of its title, illustrated with a more or less lengthy series of laudations from the Medical Reviews, in all the important daily and weekly periodicals. (Memo.: The length of the puffs is always judiciously graduated to the length of the purse.) This is the puff orthodox. Other men place their fate in the hands of their friends, who extol them as the Hunters and Harveys of their day: this is the puff modest.

It is easy to point out the undignified or discreditable modes of conducting Professional practice; but it is not so easy to correct them, or to persuade the Profession to agree to one uniform system of dealing with the public. Our Profession is, we think, somewhat unfairly contrasted with the other professions of the Church and Law with respect to its mode of charging, and wrongfully censured because it exhibits a more trading spirit. Our position is altogether different. Clergymen generally have a fixed income, which they can retain for life: give Surgeons an average income of three hundred pounds a year with the same security, and they will be soon too independent to send in "Bills of Particulars." When a living is not endowed, the Clergyman is only too glad to be paid by his pew-rents, or by sending round the plate at every Sunday service for the contributions of his flock,—a system in a measure equivalent to the mode in which a Medical Practitioner is paid by a Benefit Club. Again, as to bills,—the Solicitor does send in bills, and unconscionably long ones too, as it is the misfortune of many a trustful man to know. If his charges be fixed, it is because there is no element of charity in his dealings with his fellow-men, and because it is in the power of every man to engage his services or not, as he may please.

The customs of our Profession have grown out of ancient usages, and these, again, out of the needs and prejudices of the public. The people must be supplied with Medical aid as they require it, and must be charged according to their means; hence the diversities in the amount of requital. If a Physician can obtain a guinea fee, let him have it by all means; but if a shilling be the maximum of a poor man's ability of payment, the Practitioner is justified in accepting it.

Then there is the "drug" question, that perpetually comes to the surface in these controversies. Ought Medical Practitioners to dispense their own medicines, or relinquish this duty in favour of the Druggists? Time will settle this question; and it is much nearer a settlement now than it was ten years ago. It is probable that at least one-half of the Profession have discontinued the custom of sending in bills of particulars,—the first step to the renunciation of the practice of dispensing drugs. A considerable number of General Practitioners already charge for attendance only; whilst a more limited number take small fees, and provide the medicines without extra cost to the patient. A few practise entirely as Physicians. A great change is in progress, and, as we said when we commenced this article, the question will settle itself.

At one time, the art of the Apothecary consisted in the decoction of simples and the compounding of pills; and prescriptions were of enormous length and complexity, as if these qualities justified the skill of the Practitioner. Various causes have operated to reform this culinary kind of practice, and Medical prescriptions are becoming models of simplicity and intelligent purpose. The Pharmaceutists have, moreover, undertaken the duty of compounding for the Surgeon all the more elaborate preparations; so that the

Practitioner's familiarity with the art of boiling simples, and making extracts and ointments, is growing obsolete. There is a gradual tendency, therefore, to a simpler and less commercial mode of conducting Medical practice, and we shall not be surprised to see the custom of sending prescriptions to the Druggist, and of charging for attendance alone, established as the general rule of the Profession.

SUMMARY OF THE WEEK.

THE THAMES EMBANKMENT.

The more masters, the less authority, is a maxim of universal acceptance. It is one of the advantages of a despotism, that, there being no conflict of powers, great works are carried out with vigour and despatch. Louis Napoleon has transformed Paris during his reign; and if he had such a Metropolis as ours to work upon, what would he not do with it? As it is, we are in the hands of rival authorities, each trying to outwit or counteract the other; and the result is, that the public interests are set aside until these disputes are arranged. During the last Session of Parliament, a Committee reported upon the expediency of embanking the River Thames; and since the commencement of the recess, the Government have been in communication with the Metropolitan Board of Works on the subject. It appears, however, that there is a hitch between the Imperial and the Metropolitan Government, and matters are brought to a stand-still. The Imperial Government desire to appoint a Commission on which there shall be three Engineers of known reputation, with other persons, and to entrust to this body the duty of selecting the plan and executing the work. The Metropolitan Government object to this scheme, and say, fairly enough, that as they have been appointed to carry out the new system of Sewage for the Metropolis, and are empowered to make public improvements, they alone should be invested with any new powers that may be necessary for the execution of the scheme. So the matter stands at present; and unless one party or the other relax its opposition, nothing will be done for another year. We must confess our distrust of Government Commissions. We have had several of them, and they have uniformly failed. There were two or three Sewers' Commissions; but they did nothing but spend money and incur debts, and at last Parliament was compelled to entrust the work to the Metropolitan Board, who, it must be admitted, are now carrying it out with spirit and energy. They were a long time, indeed, arranging their plan; but they are now getting rapidly on with their work. The Government Commissions, although graced with a Stephenson and Cubitt, did nothing. The Metropolis are now rated to liquidate the cost of their blunders. It is probable that the Imperial Government wish to keep possession of the coal duty and the hackney cab duty, and fear that by committing the Embankment of the Thames to the Metropolitan Board, they will be obliged to relinquish their hold upon those funds. So they ought. It is not right that local taxes raised in the Metropolis should be expended by the Imperial Government. What would Liverpool or Manchester say to such a proposal? Let these matters be quickly settled, and the public have the benefit of the Embankment.

DEATH BY FIRE.

The Registrar-General's Return records this week several deaths from accidental burning. Science having provided adequate means for the protection of life against such a fatal contingency, we are somewhat surprised that no attempt has been made to apply them to general use. The ladies themselves are much to blame also for their absurd indulgence in those luxuriant hemispheres of crinoline in which it delights them to surround their forms. If the dome of St. Paul's were to step from its balustrade and take an airing down Ludgate Hill, it might readily be mistaken for a fashionable lady on a shopping excursion. We wish the ladies to understand that we have no ascetical dislike to their indulgence in this caprice, or any other, so far as it is innocent and unattended with danger; but we think so badly of the unreasonable extension of this crinoline mania, that if we were not a Benedict, and therefore accountable, we would willingly join an Anti-crinoline Association to put down the evil. Such an Association should be composed of bachelors, for more reasons then we can now name. Seriously, we beg to enforce our opinion, that so many lives having been lost in consequence of the undue size of ladies' crinolines, it is full time that whoever may be the rulers of fashion in these matters should seriously exert themselves to abate the folly. Crinoline has grown too wide, as beards have grown too long; and both will bear reduction without injury to grace, and with much personal advantage.

THE ABOLITION OF NEWAGTE MARKET.

We understand that there is an intention on the part of the Corporation of London to apply to Parliament, during next Session, for powers to dismarket Newgate Market, and to abolish the disgusting and pernicious nuisances connected therewith; and that negotiations are in progress with the Dean and Chapter of St Paul's, who are the landlords, for the purpose of effecting these most desirable objects. It is doubtful, however, whether the Chapter will embrace the proposals of the Corporation, as they appear to prefer the upholding of individual interests to the accomplishment of a great public improvement. We do not wish to say hard things of the Chapter, who, as Christian men, eloquent preachers, distinguished literati, and leaders of some of the great social movements now in progress, deserve to be treated with respect. Dean Milman, and Canons Dale, Melvill, Champneys, &c., are men who must be expected to take a deep interest in the moral welfare and social improvement of the humbler classes residing within their jurisdiction, and we hope that reasonable expectation will not be disappointed. Ecclesiastical Chapters have not, however, always been characterised by liberality or a leaning towards public interests; and it is possible that this of St Paul's may be tainted with some of the vices of other similar bodies. We can only say, that if it should resolve to stand in the way of the achievement of so great a public improvement, the men who compose it will be deeply and indelibly disgraced. We hope better things.

THE APOTHECARIES' DINNER.

These annual reunions have usually no interest for the Profession; but occasionally a declaration of opinion or policy is announced by some influential person present, that is calculated to fix attention strongly upon the movements and events of the time. Of course, there is no public dinner without toasts; and on this occasion Mr Green's health was proposed, in his capacity of President of the Medical Council. In his reply to the compliments of the Chairman, Mr Green could not be otherwise than complimentary in return. One good word deserves another; and Mr Green fully repaid the debt of courtesy. But Mr Green was something more than complimentary. He said, that it has "lately become the fashion in some quarters to question the fitness of such a body as the Apothecaries' Society to regulate and control the education of General Practitioners." "Lately!" Mr Green! why, the Profession have protested against the exercise of this power by the Society of Apothecaries from the first day it was granted to them. It is a chronic complaint, and requires the combined chirurgical skill of the Medical Council to cure it. We fear, however, that Mr Green will neither use the knife, nor assist at the operation. A considerable amount of panegyric followed, on the good use the Society had made of their power, which we do not deny. Infinitely better have they done in the cause of Medical education than the Council of the College of Surgeons: nevertheless, their duty is done, their day past, and the Profession desires to see the stigma of trade wiped out from its educational system. Will Mr Green help to raise or depress the General Practitioners?

TESTIMONIAL TO MR BELFOUR.

The Council of the College of Surgeons having enjoyed the services of their esteemed

Secretary, Mr Belfour, for fifty years, have resolved to signalise this jubilee of duty by presenting him with a service of plate. Whatever may have been the shortcomings of the Council during that long period, however deeply they may have on some occasions offended Professional feeling, Mr Belfour has never been accused of want of courtesy towards the Members. We are glad to hear that he will receive such a recognition of his long and faithful services, and we believe that the Profession generally will participate in this feeling.

A PATENT WAY OF POISONING.

We have extracted the annexed advertisement from the 'Times' newspaper. The advertiser has undoubtedly invented an admirable process for poisoning his patients, which we hope the latter will be made acquainted with, both in their own behalf and that of their Doctor. No public announcement could be more discreditable. Either the advertiser wishes to take advantage of the necessities of some educated Assistant, that he may convert him into an "indoor servant," or to make an "indoor servant" discharge the duty of a Dispensing Assistant in order to save a salary. From either point of view, this advertisement exhibits a mean and sordid spirit.

"Wanted, in the house of a Medical Man, a young man from sixteen to twenty, as Indoor Servant. If able to assist in dispensing, very little house-work would be required. Apply at the Library, 10 Castle street, Oxford street."

THE SPIRIT OF THE PERIODICALS.

(Continued from page 343.)

"*History.*—About three months before her admission, she was confined of her last child. The labour was a rather protracted one, and she was attended by a midwife. After the labour she was unable to retain any urine, but gradually improved, and at the time of her admission there was a mere trickling. She was sent to be under the care of Mr Baker Brown by Mr Hemming of Kimbolton.

"On examination, there was found a very small fistula at the junction of the urethra with the neck of the bladder, which could hardly be discovered. The opening had originally been much larger, but was now filled up by a very unhealthy loose granulation.

"April 26th.—The patient being under chloroform, and in the lithotomy position, Mr Brown performed his usual operation, three bar clamps being used, with iron-wire sutures. She recovered well from the chloroform; but towards the evening unusual sickness came on, which nothing seemed to allay. This continued till the 30th, when she became delirious, and on May 3rd she died, having been insensible for the last twenty-four hours, the cause of her death evidently being pyæmia.

"*Remarks.*—As soon as she was dead, I began to inquire into the cause of so unusual a sequence to the operation. I then ascertained that there was milk in the breasts. This greatly surprised me, as she had assured me that she had weaned her baby some weeks before admission, and she had also led my friend, Mr Hemming, to the same belief before he sent her to me. Had there been the slightest doubt in my mind on this head, I should never have attempted the operation until every trace of milk had disappeared, because I had long been satisfied on this head by past experience, especially in one case of death from pyæmia, which followed an operation for ruptured perinæum, where milk was still in the breasts."

A paper headed *What is commonly called Rigidity of the Os Uteri* is contributed by Dr CHARLES D. ARNOTT. He denies that there is any rigidity in these cases, observing:

"In the great majority, the os is, in reality, dilatable enough; but some of the chief elements of dilatation are acting disadvantageously, or not at all. The fluid wedge, for instance, is generally absent, the membranes having ruptured early under the influence of the strong uterine contractions, and the fœtal head is expending all its force in a wrong direction, not upon the os uteri, as occurs under normal conditions, but upon that shelf of the uterine texture it has infringed upon, and which so long must successfully resist it.

"The treatment of these cases the teaching of the schools has hitherto inculcated, I am now fully convinced, is not only inert, but highly injudicious. Bloodletting and antimonial depressants (time-honoured maids-of-all-work) have been loudly extolled as adjuvants of vital dilatability, and almost implicitly relied on. Anodynes (learnedly) to lull excessive irritability, (truthfully) a clumsy excuse to gain time, have also had their share of renown, and these again are now likely to be superseded by a more potent agent, chloroform.

"I shall not discuss in full the merits of these plans of treatment. I am, from repeated experience, as fully convinced as I ever can be of any one professional fact, not only that they are of no use whatever, but that they are positively and highly injurious. My opinion is confirmed, that the effectual treatment of these cases is by surgery alone: reduction and dilatation of the abnormally-placed os by manipulation; and in the more aggravated and resisting cases, incision of the opposing texture. Much good service may, indeed, thus be rendered, a great amount of maternal suffering saved, and infantile life preserved.

"Free lubrication of the parts having been premised, the finger is to be introduced during each pain, and the os solicited downwards and forwards, and at the same time freely dilated without any unjustifiable force. As with the prostate after the deep incision in lithotomy, so with the os in the great majority of these cases, it will be found to yield readily. Improvement commences forthwith, and all difficulty is soon overcome. In the very rare minority, incision (mere notching with a guarded probe-pointed bistoury) may be requisite in addition to manipulation, and the most intractable cases are speedily made to assume a totally different and more promising aspect.

"I am aware the proposal seems harsh, and may be denounced by the *laisser aller* school as belonging to that confessedly bad category, 'meddlesome' midwifery. I believe, however, it may be fully proved undeserving any such epithet, by the remembrance that there are cases which tax our resources to the highest extent, from the extreme anxiety generally pertaining to them, and the inefficacy of the means usually employed for their relief; and further justified by the great fact of its being merely a close imitation of Nature's own *modus operandi* under these special circumstances.

"Let us briefly inquire how this difficulty is ordinarily surmounted by Nature's efforts when unaided? Almost always, as all observant practitioners have again and again experienced, by spontaneous laceration, sometimes rather extensive, of the resisting uterine tissues; and, in spite of bloodletting, antimonials, and all other such auxiliaries, as they are inaccurately termed, scarcely ever, until this is accomplished, can she complete the process. Instances in which very extensive rupture ensues, are, with this concomitant complication, not uncommon; and many so-called cases of occlusion of the os uteri, in which incision is the only alternative, Nature having failed in effecting the necessary laceration, are probably often little more than extreme cases of the description we are now considering, in which the os, being more out of reach than usual, escaped detection.

"I have employed the practice now recommended for many years, and on many occasions I have satisfied myself of its invariable and great utility; moreover, having never observed one untoward sequence from its employment, I conclude it may be regarded almost entirely free from danger. Let it but have a fair, unprejudiced trial, and I feel assured it will so forcibly commend itself, as to assert its superiority over all other expedients."

We extract from the 'Indian Lancet' the subjoined article on the *Radical Cure of Inguinal Hernia—a New Proposal in its Treatment*—by Dr TIERNEY AITCHISON, Civil Surgeon, Jhelum.

"The object of the operation is to invaginate a portion of the skin of the scrotum into the inguinal canal, and keep it there for a time, so as to produce adhesion, thus forming a plug to prevent the descent of the gut. The only attempt at a radical cure, so far as I am aware, that had been made in this country previous to October of the present year 1858, was at the General Hospital, by my late colleague, Dr J. R. Bedford, in 1856: this, called Gerdy's operation, also consisted of the invagination of a portion of the scrotum, which was fixed by a suture, piercing both layers of skin at the apex of the pouch, and guarded within and without by a piece of gutta percha. No advantage, however, resulted from this: the small adhesion formed in the situation of the stitch gave way on its removal, and the hernia was as bad as ever.

"The principle of Wutzer's is the same; but the invagination is effected by means of an instrument made of wood or metal, constructed so as to *fit and fill up the inguinal canal as nearly as possible*.

"These last words in italics (my own) struck me particularly at the time of reading Mr Scriven's paper. It was in this that Gerdy's operation failed; hence Wutzer's method was originated, to overcome the want of opposition required to give the parts a chance of firm adhesion. But Wutzer's instrument fails here also (although in a very much less degree than Gerdy's), as seen by Mr Scriven's complaints in his paper, as well as Professor Bothmund's new contrivance of side pieces to enlarge the cylinder to the size of canal to be operated upon. "What we want, then, is an instrument of sufficient size to fill the canal, and so ensure the contact of the opposing surfaces all round." In addition to this, if we could get it, that one instrument should be capable of being applied with success to nearly every case; and what would also be of greater consequence, if this instrument, after having been applied, by its natural form, could, without the aid of bandages, keep the invaginated parts in proper apposition, as well as by its simple presence cause sufficient amount of inflammation to produce adhesion of these, without the aid of sutures.

"I think we have got the means, in a tube of vulcanised india-rubber, ending in a globular head, which should be sufficiently elastic to admit of free expansion, by the forceable compression of air in its interior, introduced at the opposite extremity from the globular head, by the aid of an insufflator.

"The method of operation would be, to introduce first of all a small cylinder of wood into the tube, as far up as the very top of the bulbous portion. This would give the means of introducing the ball of the tube, along with the scrotum to be invaginated, so far up that they would become internal, to the internal opening through which the hernia passed.

"The cylinder would now be withdrawn, and the tube and globe filled with the air, by the insufflation, to the requisite extent, and then the tube closed, either by a stopcock, or tied with cord. The insufflated head of the tube would exactly act to the invaginated scrotum, as do the contents of the hernia to the hernial sac. But in the former case we have command over the contents, and as we wish we may either increase or decrease them, and thus, with a little care, we could prevent the inflammation which would to a certain extent originate from the pressure from becoming too extensive or too great.

"But should this plan of treatment alone be insufficient for causing the requisite adhesion wished for, we might operate according to Gerdy, and then follow up by this plan of treatment. For what possibly could give us more equal and diffused pressure over the opposing surfaces that we wish to become united, than such an instrument? and if properly introduced, viz., interior to the internal opening, as well as properly inflated, I fell confident that we could have no other better means."

TESTIMONIAL TO MR EDMUND BELFOUR.—At a meeting of the Council of the Royal College of Surgeons of England on the 9th inst., it was unanimously resolved that two hundred guineas be devoted to the purchase of a piece of plate to be presented to Mr Edmund Belfour, in acknowledgment of his unvarying zeal, fidelity, and honourable conduct, and of the invaluable services he has rendered to the institution in all its departments during the fifty years, now completed, of his tenure of office as Secretary of the College.

GENERAL CORRESPONDENCE.

To the Editor of the Medical Circular.

Sir,—I recently observed in your Journal a brief but laudatory notice of a pamphlet describing some of the various forms of surgical apparatus which have been invented by Mr Eagland, of Leeds.

As Mr Eagland, from the fact of his residing in a provincial town, is probably unknown to the great majority of your readers, and as I feel myself under a heavy debt of gratitude to him for services which he has professionally rendered me, will you permit me to describe, in as few words as I can, my personal experiences of his skill?

In August, 1857, I met with a severe accident, which left, as one of its persistent consequences, an ununited fracture of the right humerus, at a point a little above the lower part of the upper third. In the course of 1858 I applied, in succession, to two of the most celebrated surgical-apparatus makers in Edinburgh and London; but neither of the splints with which they supplied me enabled me to use the arm with any material degree of additional power. On my route to Buxton, in July, 1859, whither I was proceeding in order to try the effect of the waters on a rheumatic affection of the right knee, I spent a day with my friend Mr Page, of Carlisle, who had most carefully examined and reset my arm a few days after the occurrence of the accident, and who had then expressed a decided opinion that I should never regain the full use of the limb. On again examining the arm, after nearly two years' interval, he found a far less firm ligamentous union than is usually met with in false joints, motion being allowed freely in all directions. He fully recognised the difficulties which were presented to the application of a mechanical support, in consequence of the direction of the fracture, and its proximity to the shoulder-joint,—but added, that he thought it would be well worth my while to return home through Leeds, with the view of consulting Mr Eaglaud, in whose skill and ingenuity he had extreme confidence. I took his advice, and availed myself of the opportunity of being in Leeds to see Mr Teale, and to obtain his valuable opinion as to whether I should undergo any of the various operations which had been suggested (chiefly by my younger surgical friends), with the view of promoting union of the extremities of the bones. He quite concurred in my own view of the case—viz., that in the existing state of my health any such operation would be inadmissible, but added, that he thought that Mr Eagland, for whom he sent in order that we might discuss the difficulties and requirements of the case, might be able to make a splint that would be of considerable service. The result of this conference was the construction of a simple apparatus, which, I am thankful to say, enables me, when it is applied, to move the arm to a much greater extent than I had found practicable when using either of my previous splints.

After my return to Scotland, my knee, which had temporarily improved at Buxton, grew much worse, and the case assumed all the symptoms of chronic synovitis. I need not trouble you with details of unsuccessful treatment, or with a history of the various splints, &c., which I tried at different times. Last August I proceeded to Harrogate, partly for the benefit of the waters, but fully as much for the purpose of consulting Mr Eagland (Harrogate being within an hour's journey from Leeds) as to whether he could contrive a light, but at the same time a firm, support for the knee. On hearing of my desire to see him, he at once came to Harrogate, and in two days supplied me with a splint which enabled me, for the first time for fifteen months, to walk a short distance without pain (of course with the aid of a stick) and which, by the uniform pressure which it exerts on the joint and surrounding parts, will, in the opinion of my friend Mr Teale (who kindly came over to see me), contribute materially to improve the condition of the knee.

I have shown the splint (which I have now worn night and day for upwards of three months) to many of my Medical friends, including hospital surgeons and professors of surgery, and they have unanimously expressed the highest opinion of its merits.

Under these circumstances, I trust that my Medical brethren will not think that I am acting unprofessionally in desiring publicly to express my gratitude to Mr Eagland, through the medium of your valuable Journal.

I am, &c., GEORGE E. DAY, M.D.

St Andrew's, Nov. 12.

[It is but just to Mr Eagland that we should add a few words to the foregoing letter, in testimony of that gentleman's success in adapting appropriate appliances in the case of Dr Day. When recently at St Andrew's, we had an opportunity of seeing the splints *in situ*, and can, therefore, fully corroborate the statements of our esteemed correspondent. We most sincerely hope that the improvement that has taken place will continue,—a hope that will meet with general sympathy, for Dr Day has many friends in the Profession who will rejoice in his restoration to his wonted health and strength.—ED. MEDICAL CIRCULAR.]

HOSPITAL REPORTS.

WESTMINSTER HOSPITAL.

CONSTIPATION CONNECTED WITH FIBROUS TUMOUR OF THE UTERUS.

Ann Macdonald, æt. fifty-three, widow, admitted into Hallett Ward June 19th, 1860, under Dr Basham's treatment. Suffering from constipation of bowels, and great tenderness with swelling of abdomen. Tongue moist, having a thick, dirty-white fur; pulse 100; vomiting dark, bilious matter since early part of morning; abdomen somewhat tympanitic; tenderness most marked at lower part and in the iliac region. Hands cool, clammy; temperature of body natural. ℞ Ol. ricini, ℥ss.; tr. opii, ℥ij.; conf. rutæ, ℥ij.; decoct. hordei, Oss.—pro enema. Fotus anodyn. ℞ Hydrarg. chlorid., gr. ij.; opii, gr. j.—statim, et repetat. horis 6.

21st.—Slept little in the night, during which she has been sick; vomits green, bilious-looking fluid to-day; no action of bowels; tongue dry, of dark yellow colour; swelling of abdomen increased, rather tympanitic. Enema terebinth., ℥iv.; ol. ricini, ℥ij.; decoct. hordei, Oss. Pil. opii, gr. j., 6tis horis.

22nd.—Had a restless night; pulse 100; tongue the same; sickness continues, but not violent; swelling of abdomen continues, which is very hard and tender; no evacuation from bowels. Enema sapæ tepidæ cum sodæ chlorid. ℞ Antim. potass. tart., gr. ¼; pulv. opii, gr. j.—4tis horis.

23rd.—Bowels have not been open; slept a little last night; pain not quite so violent; tongue and pulse as last reported, sickness less. Pulv. opii, gr. j., 4tis horis.

25th.—No action of bowels; no sickness; complains of cold perspiration during night; tongue dry, furred; pulse 88, very deficient in power; abdominal enlargement continues, tenderness rather less. Brandy, ℥vj., yesterday. ℞ Ammon. sesq., gr. x.; potass. bicarb., ʒj.; aq., ℥ij. ℞ Acid. tart., ʒj.; aquæ, ℥ij.—4tis horis. Brandy, ℥ij., to-day.

26th.—Pulse 96; tongue dry, and cleaning a little at the top; no action of bowels.

27th.—Last night an enema tube was passed up to about the distance of a foot into the rectum without meeting with any obstruction, and ol. olivæ ℥iv., ol. ricini ℥ss., thrown up with gruel. It returned without any fæces in a quarter of an hour. Pulse 80, scarcely perceptible; remains in a half-sleepy state, and quiet, and does not complain of any great amount of pain. Enema saponis mollis; liq. opii sedativ., ℥xv.; aq., ℥j.

29th.—Tenderness of abdomen less; no action of bowels. The nurse states that she walked across the ward last night and sat by one of the patients, walking back to bed without assistance. Ung. veratriæ had been applied yesterday to the abdomen. The ointment produced great tingling and pricking to anus (vide notes *infra*). Tongue clean; urine plentiful.

30th.—Liq. opii sedativ., ℥xv.; aq., ℥j.—h. s. Repet. enema; full diet; omit brandy. Continues the same; tongue cleaning; ointment causes tingling on abdomen.

July 2nd.—On the evening of the 30th (22nd day), after enema she had a copious motion, not particularly hard. Tongue clean; pulse 80, of much the same character; continues as previously remarked; no deficiency of heart's action.

3rd.—Ol. ricini, ℥ss. statim sum. No action of bowels since 30th ultimo; tongue rather more furred, and drier; pulse of same frequency and character. She has been in a half-sleepy state during greater part of day; disturbed sleep at night.

4th.—Had a most copious motion of bowels yesterday, and another this morning. Is out of bed, and walking up and down the ward.

5th.—Bowels open twice to-day. Tongue coated. Complains of being very weak; no appetite. Still out of bed.

6th.—Repet. ol. ricini.

7th.—Bowels open copiously after taking the castor-oil. Complains of pain remaining in the right ilio-inguinal region, where there is a distinct hard tumour to be felt. She states she almost always has a feeling of great fulness of the bladder, and desire to void its contents; but upon attempting to do so, is never able to pass more than about ℥j. of urine at a time. This gives her great temporary relief. Almost immediately afterwards has as great a desire as before. Upon making a vaginal examination, the os uteri is felt almost at the entrance of the vagina. The lips are indurated, and the uterus occupying the vagina is moveable. She would not allow vaginal examination before. A hard tumour is very manifest upon anterior border of the uterus, rendered clear by rectal palpation.

10th.—Bowels open every day. No appetite. The same symptoms referrible to micturition.

17th.—Bowels regular; otherwise continues the same. Discharged relieved.

This was, no doubt, a fibrous tumour connected with the uterus. We are indebted to Mr Mouatt, Physician's Assistant, for the above notes.

INCOMPLETE HEMIPLEGIA.

Henry Clarke, æt. twenty-three, a carpenter, residing at Woolwich, admitted May 12th, 1860, under care of Dr Pavy, into John Ward, Guy's Hospital. He had on three different occasions contracted syphilitic sores, the first about three years ago. These sores were followed by secondary cutaneous eruptions, sore-throat, &c. He was treated by mercurials to salivation, and apparently, from what can be ascertained, to an excess. He is not an habitual drunkard, although confesses to the free use of intoxicating drinks. Two years since, had an attack of rheumatism, which confined him to his bed for five months. After recovery, his right arm was not so strong as the other. He was also laid up during last winter with rheumatic fever for three months. His upper eyelid drooped eighteen months ago, and continued so for six weeks, when he regained the use of it as before. Two months since he began to see things double, and as if through a mist, with his right eye. This condition of the eye increased daily until a fortnight after, when the lid began to droop again, and so continued until admission.

Present State.—Has a well-formed head, a large scar being on the right side of the forehead. This he states to have occurred by his falling through a skylight, eleven years since: by this fall he was rendered insensible for about three hours, but experienced no subsequent ill effects. He cannot frown on the right side; the right upper eyelid has fallen, and the power to raise it is lost. The right pupil is much dilated, and the right eye itself does not move so quickly and perfectly as the left. He complains of pain over the right orbit, which is worse at night when in bed. The sight of that eye is very imperfect; there is slight diminution of sensation over the whole of the right side of the face, but more particularly just above the orbit. Tongue is turned very greatly towards the right side; speech slightly affected; taste unimpaired. The right arm is weak; finds some difficulty in raising it to a great height. No malformation of spine. At one spot over the lumbar vertebræ, there is great numbness, which extends half round the body just above the coat of the right ilium; it ceases at the median line in front. He has a slight limp whilst walking, his right foot being shuffled along. Auscultation and percussion give normal sounds over both heart and lungs. Tongue very much furred; pulse 76; skin cool; urine abundant; bowels open.

May 12th.—Empl. lyttæ post aurem dext. applic.; julep. hydrarg. bichlor. ℥j. ex decoct. cinch. ℥j. ter die. Middle diet.

16th.—℞ Potass iodidi, gr. ij.; liq. potass., ℥xx. ex inf. cascarill. ℥j.—ter die.

19th.—Bowels constipated. The super-orbital pain has now entirely ceased, and vision is more perfect.

21st.—Bowels being still constipated, he was ordered pil. cal. cum coloc. co., gr. x.

24th.—Still progressing favourably.

29th. — Constipation continues. Pulse 96; tongue furred. Complains of the numbness in his right side. Ordered pil. cal. cum coloc. co., gr. x.

31st.—His speech is much better. Sight continues to improve.

June 1st.—Pupil less dilated. Can now move the eye in any direction, except upwards.

4th.—His bowels being again constipated, he was ordered pil. cal. cum coloc. co., gr. x., statim.

9th.—This patient reports himself greatly improved. Discharged June 12th.

We have to thank Mr H. W. Lomas, Clinical Clerk, for the above notes.

GUY'S HOSPITAL.

OCT. 22ND—EXPLORATORY OPERATION UPON TUMOUR OF RIGHT BUTTOCK.—MR COCK. REMOVAL OF MALIGNANT TUMOUR OF THIGH. —MR BIRKETT.

OCT. 30TH.—REMOVAL OF PORTION OF EXTRAORDINARY LARGE FATTY TUMOUR; PART REMOVED BEFORE.—MR COCK. COMMINUTED FRACTURE OF LOWER END OF TIBIA AND FIBULA.

EXPLORATORY OPERATION UPON BUTTOCK OF RIGHT SIDE.

This was a very curious case. A tumour had been gradually forming upon the right buttock for four years, by the side of the anus. It was of very obscure character, and ultimately became of very large size. On admission to hospital, Mr Cock diagnosed it was either malignant or fatty tumour. A few days back, a large trochar was introduced into the tumour to ascertain its character. Nothing followed this exploratory puncture. The aspect of the tumour showed no discolouration. The patient being placed in the proper position under chloroform, Mr Cock made a longitudinal section over the superficies of the tumour, with the object of dissecting it away if of fatty degeneration. He then made a deep exploratory incision. Upon this being done, fluid contents of the most disgustingly fœtid character escaped with a force as if expelled from an engine. This disturbed materially the vision, habiliments and features of Mr Cock, and committed much detriment to the outer tegnments of Mr Hilton, who was *vis à vis* to the patient.

It was not ascertained that the tumour communicated in any way with the intestine, although its contents lay in close proximity to the anus and intestine. The wound, after having been filled with lint, was dressed in the usual way.

MALIGNANT TUMOUR OF THIGH.

This patient, a man above sixty years of age, had been troubled with this tumour for twenty-four years. It was seated high up on the external aspect of the thigh, nearly on the side of the large trochanter. The tumour was globular, well defined, and of the size of a large turnip. The patient said "he was of good health," and declined the administration of chloroform. Mr Birkett dissected out the tumour. Upon making a section of it, it discovered a very curious and beautiful specimen of medullary and melanoid growth, with cells. Its surface represented strongly the appearance of black and white marble; cancerous juice was discovered in parts.

FATTY TUMOUR.

We recorded the case of this patient, a man about fifty years of age, upon whom Mr Cock operated for the removal of a portion of fatty tumour, about six weeks ago. On that occasion, we described the extraordinary diffusion and dimensions of this tumour. It had now so much increased in size as to form a large collar round the patient's neck. Mr Cock now removed another small portion of this enormous fatty growth.

COMMINUTED FRACTURE OF TIBIA AND FIBULA.

A man, about thirty-eight years of age, was brought to hospital last April with comminuted fracture of lower ends of tibia and fibula. The bones were completely smashed, and the deformity was excessive. The muscles disturbed and pulled the fractured pieces of bones in all directions. To obviate this condition of things, Mr Hilton divided the tendo Achillis, and thus subdued the action of the gastrocnemius muscle. The bones by this treatment became early adjusted, deformity was removed, and good union accomplished, terminating in a limb scarcely at all deformed. About three months ago he was again admitted into hospital. He could use his limb and walk for a short distance, when great pain and irritation came on, and abscesses and sinuses formed. Mr Hilton suspected that a piece or pieces of the comminuted splints of bone had become imbedded and surrounded by the new bone. He proposed to cut in the direction of the sinuses, and explore the condition of the bone, to remove, if possible, this source of irritation. He cut through the channels on each side of the ankle, and removed with pliers a small portion of bone. Upon doing this, he discovered two small spiculæ of bone, which had evidently been detached and imbedded, as suspected, and which Mr Hilton and the other Surgeons had no doubt was the source of the irritation induced.

UNIVERSITY COLLEGE HOSPITAL.

OCTOBER 17TH.—RESECTION OF ELBOW-JOINT.—MR ERICHSEN.

OCTOBER 31ST.—EPITHELIOMIA, DESTROYING THE EYELIDS AND EYE.—MR ERICHSEN.

RESECTION OF ELBOW-JOINT.

Mr Erichsen took the opportunity of making a few observations upon resection of joints. He said that resection had completely supplanted amputation. The operation was now performed differently to what it was on its first discovery. The **H** and crucial incisions were no longer advisable or found necessary to be done. He said, the removal of the whole joint was necessary to success. Removal of parts only of the extremities of bones, and leaving cartilages, do not form good fibrous union. Fibrous union is what is desired to be obtained. By taking away the extremities of the bones, you obtain good fibrous union, giving a joint capable of flexion, pronation, supination and extension, and a very serviceable limb. Mr Erichsen made a longitudinal incision upon radial aspect of the humerus, of about five inches in length. He then dissected round, and cut into the joint—exposed the olecranon of the ulna, and pinched it off with sharp, strong nippers. The interior of joint became exposed, which was found completely disorganised and diseased. On cutting into it, the head of the radius was found surrounded by curdy scrofulous pus: this he scooped out. A very thin slice of extremity of the humerus, across the condyles, was then sawn off. He also removed a small portion of heads of ulna and radius, and other diseased parts. He explained that very little hæmorrhage attends these operations; vessels seldom require to be secured. In this case one or two had become enlarged, being seated in a boggy position. The sides of wound being brought together, water dressings were applied.

Mr Erichsen introduced the young man upon whom he had last week operated for hare-lip. It was a singularly happy case for one so late in life. By the introduction of an additional pin through the mucous membrane of the mouth, the cicatrix was level and uniform. Although so recently done, there remained a clean cicatrix and perfectly level lip, without the least deformity. We certainly do not remember to have seen so successful a case of operation for hare-lip.

EPITHELIOMIA.

This was an extraordinary instance of the ravages which malignant ulcer makes upon the soft parts, especially upon and in the region of the eye. This tuberculous ulcer has been designated differently by different surgeons. Epitheliomia, rodent and malignant ulcer, would appear to be of one family, in which lupus must be included. We understood Mr Erichsen to say that he had not before seen these epithelial cancroid growths, or a case like the one to be operated upon to-day. Mr Hutchinson gives this disease the name of rodent ulcer, and had seen and recorded many such cases, the number of which was stated. This patient, a man about thirty-five years of age, states that about four years since he had a small tumour formed upon the inner angle of the upper eyelid, which was removed, and he recovered. Mr Erichsen described it as having a distinctly ulcerous nature. It strongly resembles lupus, destroying soft parts wherever it appears and whatever it approaches. In this case it ulcerated outwards, on the eyelid, to inwards of the eye, destroying the whole organ of the eye and all the contents of the orbit. It proceeded by eating away the whole of the upper and lower lids of the eye, and progressed to the destruction of the entire globe, leaving the orbit a frightful chasm. Mr Erichsen proceeded to operate in the way he had described—to remove, by dissecting away wherever he could reach with the knife, these ulcerated epithelial growths. In doing this he encountered considerable hæmorrhage, and several vessels had to be secured during the progress of the operation. He then soaked a pledget of lint in nitric acid, and freely applied it into the chasm which the orbit formed. This he hoped would stop further ulceration. He proposed, in that case, at some future period, by the intervention of some mode of plastic surgery, to mitigate the dreadful deformity existing.

MEDICAL SOCIETIES.

MEDICAL SOCIETY OF LONDON.

MONDAY, NOVEMBER 5TH, 1860.

DR A. B. GARROD, F.R.S., PRESIDENT.

After the usual preliminary business, the President called on Dr RICHARDSON to read a paper "On Uræmia." It seems that a paper promised for the evening was not forthcoming, and that Dr Richardson had been solicited hastily by the Honorary Secretary to fill the place.

ON URÆMIA.

The Author first pointed out the analogies which exist between uræmic poisoning and poisoning by certain common narcotic substances—such as opium and belladonna—and then passed to the description of cases in which sudden symptoms of uræmia had terminated quickly in dissolution. Thence proceeding to the diagnosis of uræmia, he passed through each phase of the disorder, particularising the symptoms with much care. Three points in this part of the paper may be mentioned as of interest. The pupil, Dr Richardson has observed, is usually fixed in uræmia, and in most cases is dilated; but, he added, this rule is not without exception, for he has seen the pupil contracted to a pin's point in a case of unmistakeable uræmia. There is in some cases, as Frerichs has said, evidence of an excess of ammonia in the breath during the acute attack; but this is not universal, and hence some have denied it altogether. The reason of a difference in this respect in different cases is very simple. In persons suffering from kidney disease, and in whom uræmia is a probable occurrence, the breath at the best of times is charged with ammonia to an extent greater than is normal. In these cases the lung is supplementing the kidney, and the elimination of the ammoniacal product is, in fact, the saving clause. It is when such persons take congestion of the lung, and are subjected to diminution of excretion by the lung, that the uræmic symptoms advance; and in these cases the breath is not ammoniacal during the attack. But there are other examples, where the uræmia is sudden in its appearance, owing to sudden arrest in the function of the kidney simply. Then the breath is markedly ammoniacal in the period of the acute attack. The third fact, as diagnostic of uræmic poisoning from poisoning by the ordinary narcotics, is, that during uræmic coma the patient will often rally and regain all his consciousness for a time, sinking again into forgetfulness, and even dying unconscious in the end.

The cause of death in uræmia formed the matter of another section of the paper, and was followed by observations on treatment. In the treatment of uræmic narcotism coming on suddenly, in a person not debilitated by previous disease, and not overloaded with fat, Dr Richardson stated his belief that there was one ready and direct remedy, and that was free bloodletting. He had seen a man who had lain three days comatose and unconscious recover, under the immediate influence of loss of blood, so completely as to transact business affairs, and inquire into all that had occurred since he was struck down. Moreover, physiological reasons supported this treatment; for the bloodletting not only relieved the body from a portion of the poison, but removed the congestion of the kidney and of the other organs, and gave the permit for recovery, if recovery were possible. Thus, in animals in which artificial uræmia had been produced, the effect of frequent venesection tended greatly to prolong life. That bloodletting should

not absolutely relieve in every case was reasonable, for whether relief were obtainable or not in any case would depend upon the degree of mechanical obstruction in the kidney; for if the obstruction were perfect, no treatment would be possible, seeing that no proceeding could be adopted to supplement the kidney altogether; but if in any instance there should be but partial obstruction, increased temporarily by congestion, then the act of abstraction of blood gave the only chance that remained of removing the burthen from the excreting organ. The last part of the paper dwelt on uræmia in its forensic aspects. In many cases where death is supposed to have occurred from the effects of small doses of opium or other narcotic, he (Dr Richardson) believed that the cause was attributable to uræmia, and that so-called idiosyncrasies were probably intimately connected with renal disorder.

Dr James Bird agreed with Dr Richardson in the practice of bloodletting in these diseases. He mentioned his practice in India in confirmation. He particularly referred to the case of a General Officer in India. He was seized with apoplexy—he bled him to ʒxxx. and also applied cupping glasses. After going to Ghignee, he returned to England; was attacked with albuminaria, and was cured under the treatment of Dr Chambers and Sir B. Brodie. He afterwards died of bronchitis.

Dr Thudichum considered the term typhoid or typhus used by Dr Richardson, objectionable. The symptoms he had described did not agree and demanded another name, although names were subjects of little importance. With respect to fevers, their symptoms did not correspond with uræmiæ; they had other symptoms attending them, such as diarrhœa and others, which uræmiæ had not. With regard to the pathology of uræmiæ, urea received in the blood becomes decomposed; carbonate of ammonia is formed. A rod steeped in hydro-chloric acid shows the presence of ammonia. Dr Thudichum went rather deeply into the chemistry and analysis of urea in the blood. He said the question pathologically remains hitherto entirely speculative.

Dr Sibson bore testimony to the utility of bloodletting on many occasions. He thought, nevertheless, it was too much resorted to. It was useful to relieve congestion. Every narcotic poison induces comatose congestion. The great source of mischief in uræmic poisoning, which has not been referred to during the discussion to-night, is the brain. He had had several cases of scarlet fever lately with albuminuria. In these cases the urea affected the head. He strongly recommended the horizontal position, and the hot-air bath. It acted by producing elimination on the surface of the skin.

Dr Salter addressed his observations to some of the experiments of Dr Thudichum. He said that urea in the blood did not explain all the symptoms of uræmic poisoning. All diseases of the kidneys showed a fatty, waxy condition. Intertubular coats were found, and epithelial deposits. There exists a normal quantity of urea in healthful blood. You always have dropsy with large kidneys. The alkaline state of the blood depends upon phosphate of soda.

Dr Garrod observed that he had in practice found Dr Richardson's views correct. Uræmia does not exclusively imply the existence of urea in the blood. In some cases of cholera, urea will be found retained in the blood in great quantities.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, November 7th, 1860.

Dr Robert Barnes, Vice-President, in the Chair.

The names of the following candidates for admission into the Society were read:—Dr Charles Henry Payne, Dr Lawrence Spencer, Dr George Ritchie, and Mr John Smith Crosland Richards. These gentlemen will be balloted for at the next meeting on the 5th December.

Dr Richard Hodges related a

CASE OF LABOUR AFTER OPERATIONS FOR THE CURE OF RUPTURE OF THE PERINÆUM, INVOLVING TO A CONSIDERABLE EXTENT THE RECTUM.

This case was brought forward to show how adequate the powers of nature are to accomplish a result even under the most unfavourable circumstances. Premature labour was suggested in this case, but not adopted, and the issue proved the wisdom of the choice. The labour was not prolonged beyond four or five hours; the head of the child presented, and the cicatrices yielded to its advance, chloroform being given to further relaxation, and to relieve pain. A lateral tear, requiring a suture, occurred, which speedily united; but the central cicatrix, the result of the operations, did not give way.

Dr Richard Hodges next related a

CASE OF SPONTANEOUS EVOLUTION OF THE FŒTUS IN UTERO.

In this case the head was the original presenting part; but, by the efforts of the uterus, the breech end of the child was so acted upon as to be depressed and forced into the pelvis, the head being changed for the feet. At the first examination the head was distiuctly recognised by its firm, round, and unyielding nature, and by the hair on the scalp; but at the second examination the feet were perceived in the upper part of the vagina just through the os uteri, thus affording an example of the actual revolution of the child in the womb.

CASE OF VACCINATION, WHERE THE PERIOD OF INCUBATION WAS ONE YEAR.

In May, 1854, Dr Hodges vaccinated a little boy three years of age, but the arm did not rise within the usual period. In the May following, however, a vesicle spontaneously formed with an areola on the seventh and eighth days, gradually declining on the eleventh or twelfth; a permanent cicatrix, marked by pits, remaining, giving evidence of the genuine vaccine disease.

Dr Fawcett Battye related a

CASE OF OVARIAN TUMOUR, WEIGHING SEVENTY-SIX OUNCES AND A HALF, IN A GIRL AGED TWELVE YEARS AND A HALF, TERMINATING LIFE SUDDENLY BY ASPHYXIA.

The title of this communication sufficiently explains the nature of the case. The cause of death was due to asphyxia, arising from the unyielding nature of the abdominal walls not allowing the tumour to present itself anteriorly. Consequently, the pressure was directed upwards, and, pushed an enlarged liver, so that it encroached upon the right lung.

Dr Graily Hewitt exhibited a specimen of

MALIGNANT DISEASE OF THE OVARY.

The patient, aged nineteen, had never menstruated. She was admitted into St Mary's Hospital, under the care of Dr Tyler Smith, and was subsequently, in that gentleman's absence, under Dr Graily Hewitt. She had been ill for six months, and a growth had gradually extended upwards from the pelvis to above the umbilicus. She died, gradually exhausted, a month after admission. The abdomen was much distended with fluid, and a large tumour, weighing upwards of eight pounds, a portion of which was now exhibited, was found growing from the situation of the right ovary, adherent to the walls of the pelvis, and nearly filling its cavity. It was of a cancerous nature. From first to last the disease had existed (apparently at least) not more than about six months.

Dr J. Hall Davis presented a specimen of a

DOUBLE BATTLEDOOR PLACENTA, WITH A SINGLE UMBILICAL CORD, CONNECTED WITH ONE CHILD.

This placenta was removed after an easy labour at full term, the child—a male—having been born alive, and of the average size. On one of the masses having passed through the vulva, Dr Davis examined to ascertain the reason why the cord was still fixed internally, when he discovered a second placental body in the upper part of the vagina.

Dr Priestley showed the Casts of some Heads which had been broken up by Dr Simpson's operation of Cranioclasm.

Dr Tyler Smith read a paper entitled,

AN INQUIRY INTO THE CORRECTNESS OF THE DOCTRINE OF WILLIAM HUNTER IN REGARD TO RETROVERSION OR RETROFLEXION OF THE GRAVID UTERUS.

After giving an account of the way in which our knowledge of this displacement of the uterus has been acquired, and the opinions of ancient and modern authors, but particularly of William Hunter, upon this subject, Dr Tyler Smith proceeded to lay down his own views, and especially to dispute the Hunterian doctrine that the chief and exciting cause of complete retroversion is retention of urine and distension of the bladder. He then went on to say: "My own attention became specially directed to the subject of retroversion of the gravid uterus in the following manner:—I attended a lady—a patient of Sir Ranald Martin—who, in the unimpregnated state, suffered from complete retroversion or retroflexion. She left this country, with the uterus retroverted, to join her husband in India. She soon became pregnant, and went the full time. The question suggested itself to me, What was the condition of the uterus in this case, after impregnation occurred? And I resolved to take any opportunities which might occur to me of answering it. I have now seen a considerable number of cases in which the retroverted uterus has become impregnated, and have carefully watched the progress of gestation under these circumstances. The result has been a conviction that the most common cause of retroversion of the gravid uterus is not to be found in the state of the pelvis or the condition of the bladder, but in the occurrence of impregnation in the retroverted uterus, and in the tendency of the organ thus impregnated to grow and develop itself, during the early months of pregnancy, in the retroverted or retroflexed position. When an ovum is deposited in the retroverted uterus, the enlargement of the organ causes a greater sense of weight and pressure in the pelvis than ordinary pregnancy. The os uteri approaches the pubis, and the fundus projects towards the hollow of the sacrum. The fundus is found to enlarge considerably when examined from time to time by the finger. At length, unless the pelvis is of a very large size, the bladder and rectum are pressed upon so as to interfere with their functions, and difficult micturition and defecation, especially the former, are the results. Owing to the retention of the gravid uterus within the pelvis, there is little or no increase in the size of the abdomen. There is usually a great amount of pain and discomfort in the lower part of the back, and the sympathetic affections of pregnancy are frequently more severe than usual. Abortion very frequently occurs from the mechanical irritation of the uterus."

After making some further general observations to prove the strength of his argument, Dr Tyler Smith proceeded to say,—"In conclusion, I may observe that it seems to me the great use of the knowledge of the mode in which retroversion of the gravid uterus occurs will be in the prevention of the full retroversion, or strangulation, as I have ventured to term it, of the gravid uterus in the pelvis. As long as retroversion was supposed to take place suddenly and mysteriously, little could be done to avert it; but if, as I believe, the displacement dates from the very beginning of pregnancy, in the great majority of cases, we may do much by position, and attention to the bowels and bladder, to prevent any dangerous symptoms; and, aware of the condition of the uterus beforehand, we shall be more ready to give prompt mechanical assistance when it becomes necessary to pass the hand into the vagina to carry the fundus above the brim.

"When retroversion has existed in early pregnancy, but has been relieved spontaneously or otherwise by the ascent of the fundus, labour takes place without any unusual difficulty. We ought, however, in the management of the puerperal state, to endeavour to prevent a return of the uterine displacement. The occurrence of pregnancy is rather favourable than otherwise to the cure of retroversion. In the latter months of pregnancy, the fœtus acts as an intra-uterine pessary; the organ is strengthened, and in the return of the uterus to the size of the unimpregnated state by the process of involution we have a better chance of curing retroversion than under any other circumstances. The abdominal bandage should not be tight enough to force the uterus into the pelvis. The patient should be encouraged to lie on her right or left side, inclining to the prone position, but avoiding recumbency. The bladder should be frequently relieved, and any violent straining during defecation avoided. She should remain in bed or on a couch longer than usual, and before resuming her ordinary duties the condition of the uterus should be ascertained; and if any tendency to a return of retroversion exists, an air-pessary should be worn in the vagina as long as may be necessary to ensure a right position to the uterus.

"Several other cases of retroversion of the unimpregnated uterus, followed by retroversion in the gravid state, have fallen under my observation, besides those related in the present paper; but as they would only be a repetition of those already detailed, I will not trouble the Society with the particulars of them. What has happened in my own practice must necessarily have occurred in that of others, and probably it is only necessary that the matter should be understood for the production of a number of well-authenticated cases of the same kind by those engaged in obstetric practice. I must now leave it to the Society to decide whether the facts and observations which have been adduced do not prove that the Hunterian theory of gravid retroversion is no longer tenable; and whether we must not in future look upon retroversion of the unimpregnated state, which is well known to be a common affection, frequently admitting of impregnation, as the principal cause of retroversion of the gravid organ. In raising this discussion, I would yield to no one in

veneration for the name of William Hunter, as being undoubtedly one of the greatest and most honoured names in obstetric science."

Dr Oldham said that he had long entertained the opinion that the view of William Hunter was a mere mechanical fancy. He thought, with Dr Tyler Smith, that the original cause of retroversion of the gravid uterus was the existence of this displacement prior to conception. Such cases were very common in hospital practice, and they generally gave but little trouble. He was in the almost daily habit of seeing them do well without any interference beyond a little attention to the bowels and bladder. He confessed that he did not like the author's use of the air-pessary, for it might do harm, and in the greater number of instances mechanical attempts at replacement were unnecessary. When he found it expedient to interfere, he had for some years past resorted to a very simple but effectual proceeding. This consisted in gently opening the orifice of the vagina with the fingers, so as to allow the canal to fill with air. The consequence of this proceeding was that the vagina became much distended, and then gentle pressure with the finger upon the fundus of the uterus sufficed to push this organ upwards into the normal direction.

Dr Barnes said that he had published a lecture one year ago on this subject, in which, he thought, would be found many of the views brought forward this evening. He believed that a previous retroverted condition of the uterus might be the most common cause of this affection in pregnancy; but he was sure that it also sometimes happens from accident, and that it may take place suddenly. He had tried Dr Oldham's plan of reduction in two well-marked cases, but in both the proceeding failed to be of any service. Dr Barnes also remarked that he did not understand the principle upon which Dr Oldham's plan could be expected to succeed.

Dr Waller was happy to agree with Dr Smith. His rule in these cases was to do nothing in the majority of cases, unless the bladder and rectum got distended. He had withdrawn thirteen pints of urine in one case, which had been mistaken for dropsy, and the patient made a favourable recovery.

Dr Priestley said the effects which had been chiefly spoken of in the discussion were those which arose in the latter months; but there are other dangers which have not been noticed, and which occur in the earlier periods of gestation; especially there was the danger of abortion about the third or fourth month, and it was worth considering whether these abortions could not be prevented. Dr Tyler Smith had recommended air-pessaries, but Dr Priestley had had no experience in their use. There was often no difficulty in replacing the uterus by the finger; but it very often happened that directly the patient got up, the uterus fell back again into its abnormal position.

Dr Tyler Smith having replied to the various observations which had been offered, the Society adjourned.

OUR NOTE BOOK.

ANTAGONISTIC ACTION OF OPIUM AND BELLADONNA.

Several instances of poisoning by belladonna or atropia have now placed beyond question the advantages of opium as an antidote. These facts have moreover shown the impropriety of combining in the same prescription, with a view to rendering it more effective against pain, opium and belladonna. The 'Art Médical' and the 'Gazette Médicale de Lyon' supply us with some interesting documents on the subject.

Mr Lindsay, of Edinburgh, says M. Jules Davasse in the 'Art Médical,' succeeded in dispelling with 6 dr. of tincture of belladonna the coma induced by one ounce of a solution of morphia. Anderson likewise obtained the same result with one ounce of tincture of belladonna, in a very serious instance of poisoning with 5 drachms of laudanum. M. Cazin relates a case in which a liniment containing 1½ dr. of laudanum and ½ dr. of tincture of belladonna, in 10 dr. of sweet oil, was swallowed by mistake and gave rise to no alarming symptoms. He also prescribed with benefit extract of opium and cold affusions, for a young lady who accidentally swallowed a cup of infusion of belladonna in lieu of the same quantity of infusion of orange-leaves, and who presented symptoms analogous to those of delirium tremens. More recently, M. Béhier, in six cases of sub-cutaneous injection of sulphate of atropia for the cure of neuralgia, in all of which signs of poisoning were observed, succeeded in checking them by the exhibition of opium and of syrup of poppy.

In the 'Gazette Médicale de Lyon,' M. Perroud publishes a curious instance of poisoning by the application of a belladonna plaster, in which the symptoms yielded to preparations of opium.

The patient was a young laundross of very delicate skin, to whom the application to the epigastric region of a belladonna plaster, 4 inches by 2, had been prescribed. The plaster was applied at 3 p.m., and the next morning she awoke with a sense of general discomfort, headache, giddiness, loss of appetite, nausea unattended with vomiting, characteristic dryness of the throat, &c. These symptoms increased in violence in the course of the day, and in the evening, after seven o'clock p.m., frequent syncope occurred, followed by delirium, refrigeration of the extremities, &c. The condition of the patient was such as to occasion much anxiety, and the following medication was instituted:

The plaster was removed; an enema with 15 drops of laud. liq. Syd. was prescribed, which was almost entirely retained; and also a 4-ounce mixture containing 2 gr. of extract of opium, to be taken in table-spoonfuls every five minutes.

When the patient had taken four doses, she recognised the persons about her, and the delusions began to yield. The mixture was continued, but the doses were now given every half-hour only. On the following morning, the patient was in a perfectly satisfactory state, and despite the rather large quantity of opium taken, no signs whatever of narcotism were observable; an unanswerable proof of the antagonism of the two medicines.

The converse of the above case will be found in the 'Cincinnati Lancet,' and was communicated by M. Comégys, Professor of the Medical College of Ohio. This gentleman states that with an enema containing half an ounce of tincture of belladonna, he succeeded in restoring a man whose life had been greatly imperilled by the ingestion of two ounces of laudanum.—'Journal of Practical Medicine and Surgery.'

STATISTICS OF DIPHTHERIA. — INSUFFLATION OF ALUM AND TANNIN.

Since the debate to which a communication of M. Bouchut on the subject of croup and diphtheria gave rise two years ago, at the Academy, many works relative to this question have been published. It may perhaps be doubted whether they have led to any progress in the treatment of the disease, but it appears certain that the success alleged to have been effected by certain much-praised medications has been due to mere error of diagnosis.

Among the memoirs relating to genuine croup, or laryngeal diphtheria, we may notice a thesis by Dr Peter, formerly attached to the Hospital for Infancy. This thesis is based upon 196 cases of diphtheria, 142 of which were instances of croup and 54 of various pseudo-membranous affections. It is in the course of the third year of life that croup in these cases was manifestly most frequent in both sexes. The prevalence of diphtheria at that age is so distinctly marked and so invariable in Dr Peter's table, that it must obviously be the result of some general law. A comparison between the mortality caused by croup and that resulting from diphtheritic angina shows, beyond dispute, that death is less the consequence of asphyxia than of poisoning. With regard to tracheotomy in croup, the following are M. Peter's conclusions:

In both sexes the proportion of recoveries after operation has been slightly above one in four (1 in 3 for male, 1 in 3·7 for female children): this figure is somewhat higher than the average of success at the Hospital for Infancy.

In both sexes tracheotomy has been invariably unsuccessful when performed in children aged two and two and a half years.

It began to yield favourable results, and that but unfrequently, in subjects aged three years or three years and a half only.

Success was very frequent between four and six years for girls, and between four and five for boys.

Unfortunately, the period at which tracheotomy is most successful does not correspond with the age at which croup is most common.

Supposing tracheotomy to have been performed but in children aged three and a half, or more, the average of cures would have been but one in 2·3 operations instead of one in 3·4, and would therefore have been less considerable by one-third.

Between the ages of two and three, children who have undergone operation appear to sink under the violence of traumatic fever.

Tracheotomy has proved in both sexes more successful in March and July than in the other months; but, in general, the season does not appear to have exercised much influence.

The 'Union Médicale' has recently published two letters from Messrs Loiseau and Trousseau on the use of tannin and alum locally in the treatment of pharyngo-laryngeal diphtheria.

M. Loiseau, considering the false membranes, in all cases, to be but consequences of diphtheria, and, with the exception of croup, rather useful than injurious, provided their putrefaction be prevented, again lays stress upon the beneficial action of styptics, and especially tannin; these seem to convert the morbid secretions into an imputrescible epidermis, which affords protection to the denuded surfaces and promotes their cicatrisation. M. Loiseau performs insufflation of alum five or six times a day, and of pure tannin equally often; he states that a cure may thus be effected in three or four days, on the same principle which M. Trousseau adopted in his practice in 1828. A quotation from an article published on the subject in 1833, by M. Trousseau in the 'Dictionnaire Médical,' has elicited from the learned Professor a reply, which we reproduce, as it explains the changes his views have undergone on the efficacy of the medical treatment of diphtheria, and more especially of croup.

It is perfectly true, says M. Trousseau, at the date of September 20th, that in the epidemics of diphtheria which from 1818 to 1828 prevailed in the departments of Indre-et-Loire, Loir-et-Cher, and Loiret, the disease of the fauces readily yielded to frequent insufflation of alum, and to cauterisation with muriatic acid or nitrate of silver. It is equally true that, when the complaint was met in its early stages, four or five days were sufficient to effect a cure, excepting, of course, when diphtheria had invaded the larynx.

For ten years past, however, diphtheria has acquired in Paris and in the provinces a degree of gravity and of malignancy which it did not, by any means, possess thirty years ago; and I declare that it is now a long time since I have had the good fortune to see genuine pharyngeal diphtheria yield to treatment in four or five days. Common pseudo-membranous angina, or herpes of the fauces, may be cured in twenty-four or forty-eight hours, but not real diphtheria such as we too frequently meet with.

I resort to the same means as M. Loiseau, and perform insufflation into the throat every two hours, and even every hour, if necessary, alternating the use of equal parts of sugar and alum or tannin. From time to time, I brush rather roughly the uvula and tonsils, before resorting to insufflation, in order that the medicinal agents may come into immediate contact with the mucous surface; and I consider myself very fortunate when, after ten days' treatment, all trace of false membranes has disappeared.

In five adults whom, within the last few months, I attended with my friends Drs Bernard, Patouillet, and Blondeau, the disease lasted nine days in one case, and more than a fortnight in the others; and I repeat that it would have been utterly impossible to use with more persevering energy the remedies extolled by M. Loiseau, which I consider most useful, namely, alum and tannin.

Appealing to the testimony of my learned colleagues of the Hospital for Infancy, Messrs Blache, Bouvier, Roger, Sée, and of Dr Barthez, I find their statements are perfectly similar to mine, and that they agree with me in thinking that the singularly rapid, extraordinary, and numerous cures effected by M. Loiseau may perhaps be accounted for by his not having allowed himself sufficient time to establish an incontrovertible diagnosis.

It is difficult at first, and especially in children, to distinguish genuine diphtheria from pharyngeal herpes; and although in doubt I prescribe the local application of alum and tannin, I do not flatter myself that I have effected a cure of tonsillary diphtheria when, after twenty-four hours, I cease to detect in the throat any pellicular concretions.

We are happy to be confirmed, by so competent an authority, in the remarks we have offered above on the importance of diagnosis in the appreciation of the various remedies recommended for a disease the gravity of which, far from subsiding, seems rather on the increase, especially when observed in an epidemic form.—'Journal of Practical Medicine and Surgery.'

LEGAL INTELLIGENCE.

THE QUEEN *v.* THE BRANCH MEDICAL COUNCIL FOR ENGLAND.—Mr Lush, Q.C. (with Mr H. T. Cole) recently moved for a rule calling upon the Branch Council for England of the General Council of Medical Education and Registration of the United Kingdom to show cause why a *mandamus* should not issue commanding them to cause the name of Thomas Goulden to be entered in the 'Register.' Mr Goulden was in practice before August 1, 1815, and he claimed to have his name inserted in the 'Register,' under the 18th section of the Medical Act (the 21st and 22nd Victoria, cap. 90), which enacted that "Any person who was actually practising Medicine in England before August 1, 1815, shall, on the payment of a fee to be fixed by the General Council, be entitled to be registered on producing to the Registrar of the Branch Council for England, Scotland, or Ireland, a declaration according to the form in the Schedule (B) to this Act, signed by him, and upon transmitting to such registrar information of his name and address, and enclosing such declarstion as aforesaid." The applicant stated in his affidavit that he was bound apprentice on August 20, 1810, and served till he was twenty-one years of age—viz., till October 30, 1814, when he came of age, and commenced practice. The Medical Council did not dispute the fact that the applicant was in practice before August 1, 1815, but they said he was not of age at the time. That, however, he (Mr Lush) contended was wholly irrelevant matter.

Mr Justice Hill inquired whether there was any law which prevented him from practising before he was of age?

Mr Lush said there was not. The 55th George III, cap. 194, contained an enactment that no one, after the passing of that Act, who had not been in practice before August 1, 1815, should receive a licence from the Apothecaries' Company till he was twenty-one years of age, but it preserved the rights of those who had been in practice before August 1, 1815. The Council did not dispute that the applicant was in practice before August 1, 1815; but they said that, from the evidence laid before them, they were not satisfied that he was of age. The applicant did not know what information the Medical Council possessed, but he produced before the Court evidence to show that he was born on October 30, 1793, and consequently came of age on October 30, 1814.

Lord Chief Justice Cockburn said the Court could not try that question.

Mr Justice Blackburn asked whether there was any question about the party being in practice in his own right?

Mr Lush said the only answer made was, that he was not shown to be entitled to be on the 'Register,' as he was not of age on August 1, 1815, which, the learned counsel contended, was a wholly immaterial question.

Lord Chief Justice Cockburn: You may take a rule.

Rule *nisi* granted.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 13th inst.:—William Batho, Amesbury, Wiltshire; Chas. Hy. Bennett, Hammersmith; Augustus L. Bentham, Portsmouth; Edwin Buller, Jersey; Sidney Edward Clarke, Armathwaite, Cumberland; William John Corin, Redruth, Cornwall; George Carr Dunn, Kensington Park gardens; Delamark Freeman, Kennington; John Palmer Gannon, Oxford; George Blyth Goldie, Northumberland; George Daniel Harding, Woolwich; Charles Henry John Hovell, Canterbury; Edward Jeffery, Exeter; John Jones, Brighton; Ferdinand Ethelbert Junker, London; George Kerswill, St Germans, Cornwall; John Langdon, Yeovil, Somerset; Robert Pattinson, Wiggonby, Cumberland; George Griffith Phillips, Newcastle Emlyn; Frederick Beaufort Scott, Cheltenham; Richard Wagstaff Smith, Nova Scotia; Weston Erskine Wadley, Plymouth; Jeremias Fredrik Ziervogel, Cape of Good Hope. —The following gentlemen were admitted Members on the 14th inst:—John Bourne Bromley, Stourbridge, Worcester; William Joseph Callon, Liverpool; James Cheese, Jersey; William Hill Climo, Belmullet, Co. Mayo; Henry Davies, Crossin, Carmarthen; Thomas Finch, London; Francis Baker Fowler, Bath; William Gayton, Church street, Spitalfields; Augustus Robinson Hall, Topsham, Exeter; Marriott Hall, Sheffield; William Hoyle, Slaithwaite, Yorkshire; Joseph Laidler, Stockton-on-Tees; Henry Edward Langford, Cherbury, Shropshire; Henry Robert Campbell Litchfield, Twickenham; William Hooper Masters, Yeovil, Somerset; John Morgan, Clifton, Bristol; Robert Nash, Weston-super-Mare; John Racey, Quebec; John Scaly, Barbadoes; William Stawman, Wakefield, Yorkshire; Chas. Steele, Clifton, Bristol; Daniel Taylor, Bury, Lancashire; William Thomson, Edinburgh; Thomas William Thursfield, Kidderminster; Henry Ward, Diss, Norfolk; Henry Wheeler, Clifton, Bristol; William James Wilson, Straid, Ballynure, Antrim.

NEW FELLOWS.—At a meeting of the Council of the Royal College of Surgeons on the 9th inst., the following members the College, who had been elected Fellows at previous meetings of the Council, were admitted as such:—Henry Bedwell, Cheltenham—diploma of membership dated June 26, 1840; Robert Harrison Bowness, Poulton-le-Fylde, Lancashire—May 7, 1838; William Carr, Lee grove, Blackheath—May 29, 1837; Richard Chapman, Kirby Moorside—February 5, 1819; Robert Humphrey Cooke, Stoke Newington—February 15, 1839; John Taylor, Bayswater—June 26, 1840; Robert Hankinson Williams, Great Eccleston—May 9, 1834; Frederick Wood, St Bartholomew's Hospital—July 2, 1841.

ANATOMY AND PHYSIOLOGY.—The following gentlemen, having undergone the primary examinations on the 9th inst., will be admitted to the pass examination when eligible—viz.: Messrs W. W. Somerville, Edinburgh; L. R. H. Rouse, University College; Percy Milligan, ditto; Wm. Rayner, ditto; Muncherjee Beramjee Colah, ditto; E. H. Olive, ditto; S. J. B. Caldwell, Westminster; Fred. Lewis, Middlesex; C. F. Sutton, ditto; J. R. Brumwell, Manchester; T. V. Rayner, ditto; F. B. Eaton, Newcastle; T. M. Rouse, St George's; Samuel Swabey, Edinburgh; R. C. Price, St Mary's; W. J. Wilson, Belfast; W. H. Climo, Galway; F. E. Junker, Vienna; J. B. Yeo, King's College; Henry Goodall, Glasgow; A. C. Gray, ditto; John Martin, Liverpool; C. W. Waylen, St Bartholomew's; F. W. Brown, ditto; S. C. Hird, Leeds; William E. Stevens, Guy's; J. H. Benson, Leeds; John Harrisson, King's College; H. W. Mitnish, ditto; William Ironside, Aberdeen; Forbes Watson, St Thomas's; S. W. Fisher, Bristol; F. H. Heusman, Glasgow; Robert Winter, St Mary's; E. C. Ashford, Edinburgh.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, Nov. 8th, 1860:—John Roberts, Crwg, Carnarvon, North Wales; Richd. Griffiths, Welshpool, Montgomeryshire; William Henry Hartill, Willenhall, Staffordshire; Frederick Philip Phelps, Reading, Berks; John Warner, Leighton Buzzard, Beds.—The following gentlemen also on the same day passed their first examination:—Frederic Barnes, Charing Cross Hospital; Edmund Venning, University College.

UNIVERSITY OF LONDON.—SECOND M.B. EXAMINATION, 1860.—The following is a list of candidates who have passed the late second examination for the degree of Bachelor of Medicine:—*First Division.*—Thomas Hiron Bartleet, Queen's College, Birmingham, and King's College Medical Schools; Charles James Bracey, ditto; James Braithwaite, Leeds School of Medicine and Guy's Hospital; William Cayley, King's College; John Cooke, St Thomas's Hospital; John Easton, King's College; Henry Gervis, St Thomas's Hospital; Francis William Gibson, B.A., University College; Charles Grabham, St Thomas's Hospital; John Harley, King's College; William Sims, ditto; Eustace Smith, University College; William Spencer Watson, King's College; Robert Watts, University and Bengal Medical Colleges; Frederick Poynton Weaver, Liverpool Infirmary and Guy's Hospital; Henry Forbes Winslow, King's College; Washington Lafayette Winterbotham, University College; Edward Woakes, St Thomas's Hospital. *Second Division.*—William Hickman, University College; Reginald Croft Lever, King's College; William Pile, University College; Sydney Ringer, ditto; Joseph Rutter, ditto; George James Symes Saunders, King's College.

APPOINTMENTS.—Mr Simpson, formerly Surgeon to the Western General Dispensary and Surgeon to the Western Educational Vaccine Station, nominated by the Privy Council, has been appointed Teacher of Vaccination, under the new regulations of the Medical School of University College, at the Tottenham Court Chapel Station. The certificates of proficiency granted by Mr Simpson entitle their possessors to hold Poor-law appointments.—At a special meeting of the General Committee of the Birmingham and Midland Eye Institution, held on Thursday, November 1, Sidney E. Proctor, L.R.C.P., &c., formerly Resident-Surgeon to the Kent County Ophthalmic Hospital, Maidstone, was appointed Resident-Surgeon to this Charity.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen, having passed their Examinations, were admitted Licentiates of the College during the recent sittings of the Examiners:—John Bolland, Dublin; Thomas Clark, Blairgowrie; Thomas Smith Clouston, Orkney; William John Fairbairn, Edinburgh; Abraham Hogg, Co. Cavan; James Mathews, Co. Cavan; George Monteath, Dumfriesshire; David Robertson, Dunkeld; William Thomas Young Smith, Yorkshire; George Grainger Tandy, Worcestershire.

THE MEDICAL COUNCIL AND MR ORGAN.—On Thursday last, Mr Organ obtained a rule in the Court of Queen's Bench for requiring the Medical Council to show cause why his name should not be restored to the list of qualified Medical Practitioners.

OPHTHALMIA IN ITALY.—Of the troops of King Francis in Gaeta, more than 2,500 have been attacked by ophthalmia.

THE EDINBURGH SCHOOLS opened last week with the usual introductory lectures. The attendance is an increase on last year. Candidates for the University degree being admitted on the preliminary examination of the old system for the last time, a large number availed themselves of the opportunity. A marked increase in the number of candidates for the preliminary examination for the double qualification by the Colleges of Physicians and Surgeons proves the attractiveness of the scheme of the Edinburgh Colleges. The University address was delivered by Sir David Brewster, the well-known Principal. The address dealt mainly with questions of University reform, which has of late been so much stirred in Scotland. The Principal having maintained that he and his colleagues of the Senatus Academicus must be the safest depositories of the patronage of chairs; that the proposed association of independent examiners with the professors in conducting the examinations for degrees is unacademical and unnecessary; and that there should be one set of professors for teaching, and another set to do the thinking,—much surprise has been excited by the novelty of the views, and they have been severely criticised in the local journals. The Principal is a vigorous advocate for a University conferring degrees only on those who have taken all their education within its walls, but he did not meet the difficulty of the London University degrees being, notwithstanding, in the highest repute. The distinguished Principal concluded his brilliant lecture with a warm tribute to the labours and Christian worth of the late Dr George Wilson. The introductory lecture at the College of Surgeons was delivered by Dr Saunders, lecturer on Physiology, in the presence of the presidents, fellows, and students of the Colleges. The relation of the sciences to each other, and the importance of the study of structure and biology as the foundation of an intelligent system of therapeutics, formed the chief subject-matters of the address, and were handled by the lecturer in his usual able and unpretending manner.—A new feature in the Edinburgh School—the Sick Children's Hospital—is now in full operation; and a course of Clinical Lectures at the hospital, by Dr Matthews Duncan, is announced. Dr Keillor also announces a course on Diseases of Children.—The Session of the Medico-Chirurgical Society opened last week, under the presidency of Mr Benjamin Bell. The meeting proved of no small interest, on account of the discussion on acupressure which arose. Dr Handyside read an admirable paper on a case in which he used needles to arrest the hæmorrhage in amputation of the thigh for gangrene following injury. The vessels were readily secured by acupressure, and the needle

in charge of the femoral artery was withdrawn in forty-eight hours without any hæmorrhage following. In the discussion which followed, Professor Miller, and Drs Watson and Gillespie, took the side in favour of the ligature in preference to acupressure, giving a variety of reasons, but admitting that they had not yet tried the latter plan themselves. Mr Edwards, and Drs Handyside, Struthers, and Alex. Simpson, on the other side, spoke in favour of giving acupressure a fair trial, from what they had seen of it. Professor Simpson, the inventor of the method, was detained from the meeting. The President, in summing up the discussion, congratulated Surgery on the simplicity and value of the ligature, and suggested that possibly a combination of the two methods might be best.—'Lancet.'

MEDICAL MAYORS.—Mr Alderman R. S. Harvey, F.R.C.S. Eng. & Edin., was elected Mayor of the City of Lincoln on the 9th inst. This is the second time Mr Harvey has had the honour of discharging the duties of the mayoralty; his first election to the office was in 1843. On the same day, Dr M. J. O'Connor was elected Mayor of the ancient Borough of Morpeth; and Dr Richard Cross, Mayor of Scarborough.

BLAINE PRIZE MEDALS.—These medals, value ten guineas each, founded by the late Sir Gilbert Blaine, Bart., have just been awarded to Walter Dickson (B.), M.D., of H.M.S. Chesapeake, and William Diurs, M.D., M.A., H.M.S. Boscawen, 1858.

THE KILDARE-STREET CLUB-HOUSE, which had been purchased from the Club by the King and Queen's College of Physicians for the purposes of the College, was burned to the ground on the 10th inst., with the loss of three lives and the splendid library of the Club. We understand that none of the loss will fall on the College, as they had not obtained possession.

APPOINTMENTS FOR THE WEEK.

Wednesday, November 21.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.
GEOLOGICAL SOCIETY OF LONDON.—8 p.m.
SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—Opening Address by Sir Thomas Phillips, F.G.S., Chairman of the Council, 8 p.m.

Thursday, November 22.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.
London Surgical Home.—2 p.m.
KING'S COLLEGE MEDICAL SOCIETY.—Mr Francis Mason, "On Lithotomy."

Friday, November 23.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, November 24.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.
NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—Clinical Lecture on "Epilepsy and Paralysis," by Dr Brown-Séquard, 3½ p.m.

Monday, November 26.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.
MEDICAL SOCIETY OF LONDON.—8½ p.m.

Tuesday, November 27.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.
MEDICO-CHIRURGICAL SOCIETY OF LONDON.—8 p.m.

BOOKS RECEIVED FOR REVIEW.

On Urine. By Edmund A. Parkes, M.D. London: John Churchil.
On Infant Feeding. By C. H. F. Routh, M.D. London: John Churchill.
Anatomy of the Arteries. By John Hatch Power, M.D. With Illustrations by B. Wills Richardson, F.R.C.S.I. Dublin: Fannin and Co.
On Stopping Teeth, &c. By Sidney Longhurst. London: H. Bailliere.
On Infantile Mortality. By W. T. Gairdner, M.D.
The 'Dublin Quarterly Journal,' November.
Transactions of the Pathological Society of London, vol. xi.
Clinique Médicale sur les Maladies des Femmes. Par M. Gustave Bernutz et M. Ernest Goupil. Tome Premier. Paris: F. Chamerot.

NOTICES TO CORRESPONDENTS.

F.R.C.S.'s letter on the Liverpool case, received. The copies have been sent.
Mr WELCH.—Certainly.
A SUBSCRIBER.—The hyposulphite of soda has been used successfully in cases of sarcina ventriculi. The dose is about ten grains. Dr Jenner prefers the sulphite in these cases, as it is not so readily decomposed.
Dr H. L.—The newspaper, with enclosures, received.
Dr EDWARD B.—1st. No.—2nd. No.
A FATHER.—We are unable to answer the questions more explicitly than has already been done in this Journal. The Regulations appear to us clear enough. You should write to the authorities.
KAPPA.—We do not think you are right in saying that Medical men should not be Registrars of Births, in consequence of the favouritism they may exercise when they give the Letter of Instructions for Vaccination. A lay Registrar could exercise the same unfair influence; and, moreover, he would not be liable to the restraint of professional opinion. If a Medical Practitioner abuse the privileges of his office, he deserves much censure; but we do not consider the fault of one man a sufficient reason for excluding Medical Practitioners generally from the possession of this office.
MEDICUS (Hull.)—1st. Yes.—2nd. You should write to the secretary of the office: we believe the office to be solvent.
L. L.—We recommend the book.
BARBAROSSA, on "Beards," received. We apprehend that most of the bearded philosophers you name owe that ornament more to the fancy of the artists who sulptured their busts than to the "ordination of Nature." We do not know much about the "ordination of Nature" in these particular instances, but we should like to know your authority for saying that Plato wore a beard. Diogenes, you may remember, put a *plucked* capon on the table, saying, "Behold Plato's man!" The argument, indeed, does not go for much; for Mr Green might as well exhibit a plucked candidate at the College as the last embodied specimen of the Platonic philosophy.
A STUDENT.—Received, with thanks.
A COUNTRY SURGEON.—Yes; at St Andrew's.
Dr WARD'S request shall be complied with.
Mr PORTER.—Note received.
Mr SIMPSON and Dr PROCTOR.—Communications received.
A PUPIL.—The Regulations of the Apothecaries' Society recognise the date of indenture of apprenticeship as the commencement of professional education: you would, therefore, come under the present regulations.
SANITAS.—Received.
Mr ARTHUR B. BROWN.—The Report has been received, but was too late for insertion in the present number.

The London Surgical Home,

FOR DISEASES OF WOMEN,
16 Stanley terrace, Notting hill, nearly opposite St John's Church.

MEDICAL OFFICERS.
PHYSICIAN:
T. Hall Davis, M.D.
SURGEONS:
I. Baker Brown, Esq., F.R.C.S.
T. W. Nunn, Esq., F.R.C.S.
ASSISTANT-SURGEON:
Philip H. Harper, Esq., F.R.C.S.
VISITING-SURGEONS:
W. F. Wratislaw, Esq., 1 Archer villas, Westbourne grove West.
G. Spencer, Esq., 1 Horbury terrace, Notting hill.
Dr Giles, Norfolk terrace, Westbourne grove West.

This Institution is established for the Treatment of Surgical Diseases peculiar to women. It contains twenty beds. A small sum is paid by each patient, weekly, towards the expense of the Institution, the services of the medical officers being entirely honorary.

*** All qualified Medical Men are admitted to see the practice on Thursdays, at 2 p.m., on application to one of the Medical Officers at "The Home."

J. A. TAWNS, Honorary Secretary.

Society for Relief of Widows

and ORPHANS of MEDICAL MEN in LONDON and its VICINITY.—Instituted 1788.—The Members are reminded that a QUARTERLY COURT of DIRECTORS will be held on the 5th day of DECEMBER next, at which Candidates for Admission into the Society can be proposed. It is desirable that the form of proposal be filled up and forwarded to the Secretary a few days before the Meeting. The forms of proposal may be obtained of the Secretary. The benefits of the Society are restricted to the families of deceased Members of not less than two years' standing.

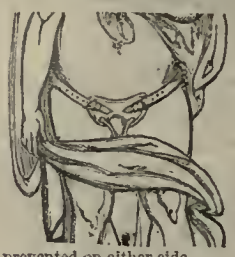
The Secretary attends at the Office every Wednesday and Friday from four to five o'clock.

S. W. J. MERRIMAN, M.D., Secretary.
53 Berners street, W.

BY ROYAL LETTERS PATENT.

Lindsey's New Patent Truss,

suitable for Right or Left, and Double Hernia WITHOUT STEEL SPRINGS OF ANY KIND.



The Faculty are invited to Inspect Lindsey's NewTruss, highly recommended for its extreme simplicity, ease, and efficiency, especially in cases where a Steel Spring Truss cannot be worn.

It consists of a plate of a light material and convenient form, and a soft or an elastic waist-belt, by which pressure (regulateable) is applied to BOTH abdominal rings, by which any descent of Hernia is prevented on either side.

For all cases of RECENT and incipient Hernia, Lindsey's Patent Truss is the best form of support, being at once curative and preventive.

A full descriptive Circular, post free, from the manufacturer,

MARK JOHN LINDSEY,
37 LUDGATE STREET, ST PAUL'S, LONDON.

A FIRST-CLASS SILVER MEDAL. PARIS, 1855.

S. Nye and Co. beg to call

attention to their

SMALL FOR DINNER &c.

MINCER THE TABLE, &c.

This little machine is for the use of those who cannot properly masticate, and who, in order to preserve health, should have their food thoroughly minced. As an aid to digestion it is invaluable, being adopted for hot or cold meat, etc., and very efficient and rapid in its operations. Price 30s.

TESTIMONIAL.

"12 Norfolk Villas, Bayswater.

I have had one of your Mincing Machines for the Dinner Table in use for some time, and find it everything that can be wished. I recommend it to all my friends who suffer from indigestion. Yours obediently,

MESSRS NYE and Co. T. SAUNDERS.

LARGER MACHINES for Kitchen Use, for Families, Hotel-keepers, Pastry-cooks, Butchers, etc., effectually and quickly mincing all kinds of meat and vegetables, for soups, etc., forced and potted meats, and a variety of dishes; also for making sausages, cutting, mixing and forcing into the skins at the same time. Price 30s., 42s., and 63s. Testimonials Free.

S. NYE'S PATENT FOR COFFEE, ETC.

IMPROVED MILLS, PEPPER, SPICE, ETC.

Are the best and most convenient ever offered to the public. Price 8s., 10s., and 14s.

"At once the best and most convenient mill of its kind now in use."—'Family Herald.'

DEPOT AND MANUFACTORY,
79, WARDOUR STREET, LONDON.—W.

Child's Patent Electro-Gal-

VANIC and METALLIC BRUSHES, for all Neuralgic and Rheumatic affections, preventing the hair becoming grey; no trouble in use, effect certain.

CAUTION.—Be sure to see that "Child's patent" is on each brush. Parties have been much disappointed by buying inferior brushes, which not only destroy by breaking the hair, but are useless for the purpose of restoring and preserving it.—Sold by all chemists, perfumers, etc.

Manufactory, 21 PROVIDENCE ROW, FINSBURY.

Nervous and Mental

DISORDERS.—Shillingthorpe Hall, near Stamford, for many years the residence of the late Dr WILLIS.—Dr GARDINER HILL, late of Wyke House, Isleworth, and formerly of Lincoln, has fitted up the above mansion, with its extensive pleasure-grounds, for the residence and cure of Ladies and Gentlemen mentally afflicted. Patients reside with the family.

Parnell's Patent Real

DETECTOR LOCKS,
FIRE AND THIEF PROOF SAFES, DEED AND CASH BOXES,
ARE THE SAFEST AND CHEAPEST FOR ALL PURPOSES.
Selected by the Board of Trade.
Street-door Latches, with two small keys, 7s. 6d., warranted secure.
Fire-proof Safe, with drawer and patent lock, £5. 5s.
DEPOT, 283, STRAND,
Opposite Norfolk street, near Temple Bar, London, W.C.
Illustrated Lists of Prices gratis.

THE PARASITICAL DISEASES OF THE HEAD AND FACE.

By GEORGE ROSS, Esq., M.D., &c.,

Author of the 'Constitutional Relations of Diseases of the Skin.'

There are no diseases more frequent or intractable than those which attack the scalp. It also happens that there are few diseases that affect the integument of other parts of the body that do not also break out either on the head or face. Hence the diseases of these regions are to a considerable extent typical of cutaneous affections generally. When, however, one of the ordinary forms of cutaneous disease appears on the scalp, it is more obstinate there than on other parts; and if the face should be also implicated, the disease causes the patient much deeper anxiety. A red patch of psoriasis on the body may be borne with comparative equanimity, but the apprehension of a permanent disfigurement of the face from the same disease excites the profoundest alarm. Besides, the uneasiness and pain accompanying affections of the delicate cutaneous surface of the face are much more acute than when the same diseases attack other parts, owing to the constant irritation caused by wind, dust, and the solar rays to which the face is exposed. These causes are also apt to render the process of cure more difficult and protracted.

The forms of disease which will now especially engage our consideration have been, until the last few years, little understood. The words Ringworm, Scall Head, Baldness, seem to be sufficiently intelligible; but it is only necessary to look through the several treatises on Diseases of the Skin to discover that there is a wide disagreement of opinion among their authors as to the nature and relations of those affections. Much of this contrariety of opinion is, no doubt, owing to the pedantic fondness for classification which has hitherto prevailed, and from a perverse desire to do that which Nature everywhere abhors—namely, to fix a definite limit and character to each classified type of disease. I do not deny the uses of classification; but it must be taken for what it is worth, and not set up as a substitute for Nature.

As an illustration of this statement, I may observe that the most recent authorities differ widely as to the pathological affinities, and therefore the scientific nomenclature, of ringworm. For instance, Dr Neligan says that it is a herpetic or vesicular eruption, and calls it *herpes circinnatus*. Mr Wilson regards it as a peculiar affection of the hair itself, and describes it under the name of *trichosis furfuracea*. Cazenave nearly agrees with Neligan, and styles it *herpes tonsurans*; but his English Editor, Dr Burgess, denies that it is a vesicular eruption at all, and substitutes a new chapter for the original one by Cazenave, and, classing the disease with the porrigoes, names it, after Wilson, *Porrigo Scutulata*. Dr Hughes Bennet rejects the term Porrigo altogether. I might cite others—Gibert, for example, who calls it *pityriasis decalvans;* but enough of these discrepancies. Nevertheless, the disease, as Nature presents it in its more advanced stages, is well known and described by each of these authors; it is the classification that creates the confusion and the obscurity. Scall head has been the subject of just as much difference of opinion.

If Medical Practitioners are so much at variance concerning the nature of these diseases, we cannot be surprised if the public make yet greater mistakes. Ringworm and Scall Head are phrases employed haphazard to describe very different forms of disease.

Where authors differ so much, our choice of a technical term is surrounded with perplexity. I do not deem it necessary, however, to adopt a new phraseology, the old terms answering the purpose of this dissertation for all practical ends. I shall therefore designate Ringworm under the term *Porrigo Scutulata*, Scall Head under that of *Porrigo Favosa*, and Alopecia or Baldness under that of *Porrigo Decalvans*. Under these several terms I intend also to distinguish the various diseases that resemble the characteristic affections.

I regard these forms of disease as essentially the same—

1st. Because of their seat—in the hair and *hair follicles;*

2nd. Because of the peculiar *tuberculous exudation* attending them;

3rd. Because of the presence of *vegetable parasitic growths;*

4th. Because of their *contagious* nature.

These combined phenomena afford sufficient reasons, I think, for regarding these affections as members of one family. I shall not now dilate upon these several points; but I may observe that these four characters are significant of a series of pathological conditions, commencing with a depravity of the constitution of a strumous nature, which leads to a degeneracy of the nutritive functions of the skin and hair follicle, and an amorphous exudation within and around them; which exudation becomes a nidus for a foreign growth, and this in its turn confers on the disease a contagious quality.

RINGWORM (PORRIGO SCUTULATA).

This affection attacks young children, and but rarely until after the first dentition. It commences very insidiously, at first creating little inconvenience beyond a slight tingling, and therefore escaping notice until it is well developed. When it occurs on the head alone, it is seldom observed until the rings are of some size; and even when it appears first on the face, it is usually regarded as an ordinary tetter, and nothing is done until the constant scratching of the child draws attention to the head, when generally three or four irregular rings are found, and medical assistance is sought. Thus the first stage of the disease is overlooked.

We can, however, track the progress of a case of ringworm from its earliest origin, in an ordinary case, by noticing the growth of a new ring. At first a small red patch is noticed, then pimples appear at the edges of the circle: these are minute vesicles, which, at the end of about three days, break, and a film of scurf forms at the apex of each pimple. One or two hairs spring from each point, and are surrounded with this furfuraceous matter, which can be readily picked off, when the root seems a little raised and reddish. By the confluence of these pimples a ring is formed, which may vary from a quarter of an inch to an inch in diameter. Sometimes a much larger magnitude is attained. The interior now becomes paler, and at this stage it is smooth, dry, scurfy, and papillated; the hairs, sometimes detached and sometimes in bundles, being broken, shrivelled, lighter than natural in colour, bent the wrong way, and twisted. The hair in this condition has been likened, very appropriately, to tow. The external ring is formed by the diseased roots of the hairs in the condition already described; and the skin is red, more particularly so on the outer side, where the disease extends. If the scalp has been kept clean, these characteristics are very observable.

The disease is now accompanied with troublesome itching, which induces scratching of the papillæ: these become irritated, and eventually a greyish crust forms on the patches. This crust is composed of the same furfuraceous scales that surround the roots of the hair, mixed with a peculiar exudation and the broken fragments of the hair, which are seen rising through it or matted in the mass. The dry, worm-eaten look of the patch, and circular form, have given rise to its characteristic designation, Ringworm.

Neglect of the disease, a bad strumous constitution, and perpetual tearing with the nails, sometimes cause pustules to form, from which there is a copious and offensive discharge. The head becomes scabbed, and the child is a miserable object. This, however, may be considered to be a degenerated condition of the disease.

When the disease attacks the face, neck, or shoulders, the rings are red, and covered with a fine scurf; they sometimes spread rapidly.

Pathology of the Disease.—With the aid of the microscope, recent observers have thrown much light upon this affection. The characteristics of the disease are a formation of a number of small nucleated cells, which do not assume the plant-like character observable in favus, but which, like favus, are generally considered to be of a vegetable nature. Mr Wilson, however, denies this, saying that they are a degeneration of the granules of the hair-cells, from which the fibrous portion of the hair is developed. He explains the death of the hair, and the formation of these abnormal nucleated granules, by the morbid change that has taken place in the constitution of the original granular cells. The hair is composed of an outer cortical sheath, a middle fibrous structure, and an internal medullary portion. Mr Wilson says that neither the cortical nor medullary portion is apparently diseased; but this opinion must be erroneous, as the cortex becomes dry and brittle, having the same characters as diseased epidermis, and the change in the colour of the hair evidently shows that the pigment granules constituting the pith must have undergone some alteration. The fibrous structure is composed of two layers, an external and internal: the external is "entirely formed of transparent globular nucleated granules, closely packed together, and constituting a tesselated structure;" and it is the change produced in these granules, Mr Wilson believes, that constitutes the disease. All other dermatologists, however, unite in the belief that these granules are of a vegetable nature; an opinion which I think there are sufficient reasons for accepting. Dr Neligan, however, does not allude to the existence of these cryptogams. I shall enter further into this part of the subject when treating of Porrigo Favosa, or Scall Head.

Ringworm is, I have, no doubt, a contagious disease. I have seldom seen one child in a family attacked by it without one or two more also suffering. Yet rarely more than two or three, even in a large family, will be attacked at the same time, because there will not be more than that number at the proper age or in a suitable condition to take the disease. In a school I recently visited, several children were obliged to leave in consequence of this complaint. There are many medical men who, whilst they admit the dissemination of the disease, deny its contagiousness, and explain its propagation by the assumption that the children at the time were all living amid the same external conditions, and had therefore acquired a similar constitutional peculiarity. It seems, however, rather odd that these children should have fallen into the same state of constitution just at the same period. It is more reasonable to admit the contagiousness of the complaint, and it is highly probable that the vegetable spores are the principal means of its conveyance. There is no other satisfactory way of explaining its dissemination in day-schools, which are attended by children of different families and different modes of life.

(To be continued.)

THE SPIRIT OF THE PERIODICALS.

The 'Lancet' opens with a Lettsomian Lecture, by Dr Pavy, on *Certain Points connected with Diabetes.* We extract it:

"In approaching the subject of 'Sugar in the Animal Economy,' it is necessary to place ourselves in the most guarded position. Fallacies arrive through such unexpected and multifarious channels, in researches on this point, that it is requisite to be especially cautious in dealing with the experimental results that may be obtained. The relations of sugar have certainly not yet been fully extricated from the deeper recesses of organic chemistry belonging to animal life; notwithstanding it seemed a short time since that our knowledge was complete, or nearly so, and that the whole pathology of diabetes was on the brink of disclosure. But a little more, indeed, than ten years back, the discovery of a sugar-forming function for the liver was announced. This discovery appeared to rest upon irrefutable grounds, and rapidly obtained an established footing in all our text-books on Physiology. The doctrine of gluco-genesis had become at last so familiar as an admitted fact, that one scarcely thought of stopping to question further its substantiality.

"My own impression in favour of the glucogenic theory was so strong, that for some considerable time I did not give the importance that was due to a result I had obtained which did not accord with our preconceived views. I felt inclined to attribute what I observed, rather to some source of objection in the experiment, than to look upon it as controverting the position we held. At last, however, growing dissatisfied at not being able to account for what I saw, I resolved to commence a thorough investigation to discover, if possible, the cause of my result. I found there was not the source of fallacy I was contented before in supposing might exist. From that moment I have advanced step by step, as my experiments have directed me; and from the force of the evidence that has presented itself, I have been involuntarily led from the position of a strong advocate to that of an adversary of the glucogenic theory. Disinclined, at first, to regard what I saw as constituting a valid objection, I have since been compelled to submit to evidence, which, I can only say, having convinced me, will, I believe, prove convincing to others. Much of this evidence, in as far as it is immediately connected with my subject, I shall have to advert to as I proceed, and it is my intention to show the experiments upon which my statements are founded.

"I cannot refrain from mentioning at the outset that it is with the greatest deference I stand at variance on this subject of gluco-genesis with so distinguished a physiologist as Bernard. I am satisfied the liver is not specially intended as a sugar-forming organ; but whatever may ultimately prove to be the natural purport of the so-called glucogenic matter existing in it, to Bernard will always belong the credit of a great and important discovery.

"Of the varieties of sugar, it is the glucose, or grape-sugar, that we shall have to deal with in these lectures. Now, as it is of the greatest importance that we should possess information about the means adopted for recognising our agent, I will first speak of the tests that are resorted to for determining its presence and its quantity. Happily, here we do not encounter any difficulty, for grape-sugar is almost as easily detected as any inorganic material, even when present in an exceedingly minute quantity. Numerous tests have been from time to time recommended, but the following are those that, on account of convenience or otherwise, are generally used:—

"Moore's test consists in treating the specimen with a solution of potash, and then boiling. The alkali decomposes the sugar, resolving it into a dark-coloured substance, which renders the liquid more or less of a sherry or brownish hue. I do not consider this test a desirable one for physiological purposes. Where the quantity of sugar is large, as in diabetic urine, the effect is so strongly marked that there cannot be any mistake in recognising it; but where only a minute quantity of sugar is present, there is only a shade of difference to discriminate, and, with the best intentions, we may often be deceived, where only shades of difference in colour are concerned. What, in physiology, we require is something giving a more decided 'aye' or 'nay,' and this we get with the various copper tests and with fermentation.

"In using Moore's test for the detection of diabetes, a drachm, say, of urine is treated in a test-tube with about half its bulk of liquor potassæ, and boiled for a couple of minutes over a spirit-lamp. It must be borne in mind that a fallacy—and I have frequently seen it—may occur. If the liquor potassæ have been kept in a white or flint-glass bottle, it becomes contaminated with lead. Lead may also be abstracted from the glaze of an earthenware dish, in which the potash may have been boiled or evaporated down. At all events, from whatever source lead may have been derived, on boiling liquor potassæ contaminated with it with any organic compound containing sulphur, the sulphur is liberated, and, combining with the metal, produces a more or less dark-coloured liquid, according to the amount of sulphuret formed.

"Amongst the copper tests we can have our choice; but in all, the principle of action is the same. Free protoxide of copper is present, which, on being boiled with grape-sugar, loses half its oxygen, and is thrown down as a yellow, orange-yellow, or orange-red precipitate, according to the amount of sugar present, which possibly determines the state of hydration of the deposit. A liquid containing a large proportion of sugar gives an orange-red deposit; whilst, when there is only a slight proportion of sugar present, the sub-oxide thrown down assumes a yellow colour.

"In Trommer's test, the oxide of copper is set free at the time of application. A drop, or a couple of drops, of a moderately concentrated solution of sulphate of copper are let fall into the specimen to be tested, and then liquor potassæ is added in considerable excess. The precipitate at first thrown down on the addition of the alkali is redissolved if sugar be present, and a deep-blue liquid is the result, which, on boiling, deposits the reduced or sub-oxide precipitate. The objection to this test is, that it is not so convenient in practice as the copper solutions to which I am about to refer; and where only traces of sugar are present, they may escape detection, on account of undissolved protoxide obscuring a slight production of the reduced oxide.

"Of the solutions of copper, Barreswil's liquid is by far the most celebrated. It is this form of copper test that has been employed by Bernard in his researches. Reduced to our English scale of weight and measurement, it is thus composed:—

Bitartrate of potash (cream of tartar)	960 grains.
Carbonate of soda (crystallized) ...	960 ,,
Caustic potash (potassa fusa)	640 ,,
Sulphate of copper	320 ,,
Distilled water	20 fluid oz.

"These materials are to be dissolved, mixed, and the resulting blue liquid to be filtered.

"Barreswil's liquid is thus a rather complex solution. Essentially it consists of oxide of copper dissolved in an alkali by the presence of an organic material (tartaric acid), which does not occasion its reduction at the temperature of ebullition. It is the property of the protoxide of copper not to be soluble in an alkali unless some form of organic matter be present. Hence the necessity of the tartaric acid, or some such agent, in the cupro-potassic solutions. But why use the bitartrate of potash, which calls for the employment of the carbonate of soda to neutralize its excess of acid? It is more simple to take at once the neutral tartrate of potash, and then the carbonated alkali may be dispensed with. Fehling's solution is of this description, and consists of sulphate of copper and tartrate of potash, with soda as the alkali.

"I can recommend the following as a simple method of preparing a copper solution for use in clinical practice in the detection of saccharine urine. Take five grains of sulphate of copper and ten grains of tartrate of potash, and dissolve in two drachms of liquor potassæ. A clear deep-blue liquid is formed, which is quite as efficient as any other kind of cupro-potassic test. The liquid, however, that I use and keep ready prepared in my laboratory is made with a larger proportion of potash than what is contained in the liquor potassæ—a condition necessary to enable the test to be preserved in an efficient state. The following are the proportions used:—

Sulphate of copper	320 grains.
Tartrate of potash (neutral)	640 ,,
Caustic potash (potassa fusa) ...	1280 ,,
Distilled water	20 fluid oz.

Dissolve each in a separate portion of the water, then mix the sulphate of copper and tartrate of potash, and afterwards add the alkali.

"The precipitation of sub-oxide from any of these copper solutions on boiling must not be looked upon as affording an infallible indication of the presence of sugar; neither, on the other hand, must the absence of a precipitate be regarded as absolutely proving the absence of sugar. Such a remark must seem materially to detract from the value of testing with a copper liquid; but, bearing in mind certain considerations, I do not think there is much chance of falling into error, and certainly the copper is the most useful test that we have.

"It is said that glycerine, tannine, cellulose, leucine, uric acid, and chloroform are each capable of producing, in different degrees, a reduction of the oxide of copper. Chloroform certainly exerts a strong reducing effect. Uric acid I have observed to occasion some deposit of red oxide; and from cotton I have obtained just a trace of precipitate. But the glycerine I have tested has not yielded the slightest vestige of reaction. A circumstance, however, of great importance is, that if a copper solution be kept for any considerable period, and particularly if exposed to light, it will of itself deposit some red oxide on boiling. Hence, unless the solution have been recently prepared, it should be tested, by boiling a little, alone, from time to time; and if it should be found to give a precipitate, a fresh addition of potash will restore it, rendering it again as fit as ever for use.

"But under certain circumstances no deposit of sub-oxide will take place, although sugar may be indisputably present. Ammoniacal salts have the property of occasioning this. I have frequently noticed, where an ammoniacal odour is evolved on boiling a specimen with the blue liquid, that at first there has been no perceptible change; then a change of colour, without any precipitation, has taken place; and if the boiling has been continued so that the potash of the blue liquid has expelled the whole of the ammonia, a considerable deposit of sub-oxide has afterwards fallen. The presence of albumen interferes with the proper reaction of our copper test; I expect, on account of the ammonia evolved as the result of destruction by the potash in the test. In a case of apoplexy where the urine was albuminous, I tested for sugar, expecting to find it, because there was sudden and great congestion of the circulation. The action of the test was obscure; but on boiling the urine and filtering before applying it, a neat precipitation of sub-oxide occurred.

"With a fluid like blood, a process of preparation for testing is of course absolutely indispensable. Boiling does not get rid thoroughly of the albuminous and colouring matters; its alkalinity enables the liquid to retain some of these. The cautious addition of acetic acid to neutralisation will effect their entire precipitation; but a little too much acid produces the condition that was intended to be removed. I consider this process troublesome, and always resort to the use of the sulphate of soda—a material which does not in the slightest degree interfere with our test, and which furnishes us with a perfectly clear liquid from the blood. The blood is simply mixed with about an equal weight of sulphate of soda, and heated to effect coagulation in a small porcelain capsule. Thrown on a filter, a limpid transparent liquid immediately runs through.

"Bernard has more recently recommended animal charcoal for separating albuminous and colouring matters from a liquid, where we are desirous of applying the cupro-potassic test. According to Bernard, it is the property of animal charcoal to abstract certain materials and not others from a liquid. Glucose is a substance which it does not remove, but the albumen and colouring matters are completely separated by it from the blood, albumen and uric acid from urine, and even the caseine and fatty matter from milk. It is sufficient, therefore, to treat an animal fluid with the necessary quantity of animal charcoal; and upon filtration a clear liquid will run through, which retains any sugar that might have been present, although deprived of many other substances.

"A solid substance may be prepared for testing, either by making a plain decoction of it, or else by pounding it in a mortar with the sulphate of soda, heating, and filtering in the same manner as with blood.

"Although just a point of doubt might be attached to the indications afforded by the other tests, yet with the fermentation test we have been hitherto accustomed to look upon its reaction as perfectly characteristic of the presence of sugar. It seems, however, from the researches of a French chemist, M. Berthelot, who has recently devoted much time to the chemistry of the sugars, and whose statements are entitled to our greatest consideration, that there are other substances besides sugar—viz., glycerine, mannite, dulcine, and sorbine, which are capable of undergoing the alcoholic fermentation with yeast. Alcoholic fermentation, therefore, can no longer be regarded as affording an infallible indication of sugar.

"In applying the fermentation test, it is necessary that the yeast should be thoroughly washed before use. Yeast, as purchased, will undergo a considerable fermentation alone, and even after being well washed I have found it give rise to the evolution of a slight amount of carbonic acid. In fact, the fermentation test in my hands has not proved susceptible of that delicacy and absolute certainty I could have desired. The nature of the gas evolved may be determined by the action of potash, and the presence of alcohol in the liquid may be shown by distillation, and then mixing the distilled product with unslacked lime, and heating in a convenient apparatus for igniting the vapour that passes over.

"It now only remains for me, in this preliminary part of my subject, to speak of the mode of conducting the quantitative determination of sugar. The best process I know of is with the copper solution, and this, I am satisfied from considerable experience with it, is susceptible of the utmost delicacy and precision. We cannot separate and weigh the sugar as the chemist does with an inorganic material; but we estimate its amount by its reducing or deoxidizing effect on a copper solution of determined strength. The liquid I employ—that composed of potash, tartrate of potash, sulphate of copper, and water, in the proportions I have already given—is of such a strength, that 100 minims of it are exactly decolorized by half a grain of the purest well-dried grape-sugar that I have been able to obtain. In other words, half a grain is the exact amount of sugar required to convert the oxide into the suboxide contained in 100 minims of my blue liquid. To give an example, I will describe how I proceed in the case of diabetic urine. The quantities are measured in graduated tubes, drawn at one end to a point so that liquid may be dropped as required. One hundred minims of the blue liquid are taken, and a mixture of one part of urine with five of water (because the urine is too concentrated alone) allowed to fall into it drop by drop whilst kept boiling in a small porcelain capsule over the flame of a spirit-lamp or gas. As soon as the blue colour of the copper solution has been completely removed, the operation is at an end. The amount of diluted urine employed can be read off, and will contain an equivalent to half a grain of glucose.

"Should the fermentation test be used quantitatively, according to Dr Christison, every cubic inch of carbonic acid evolved corresponds, in round numbers, to a grain of sugar; or, more precisely, forty-seven cubic inches of gas are equivalent to forty-five grains of sugar.

The same journal contains a report of the Oration delivered by Mr Henry Thompson at the commencement of the Session of the Harveian Society, and a continuation of Dr Stephen H. Ward's *General and Clinical Remarks on Scurvy*, from which we will reproduce a quotation in our next Number.

Mr Baker Brown continues his reports of *Eleven Cases of Vesico-Vaginal Fistula* in the same journal. We quote the cases now reported:

"Case 5. — *Vesico-Vaginal Fistula; two months' duration; two operations; cure.* —Mrs B——, a lady from Berkshire, aged thirty-seven; three children.

"*History.*—With her first child she was in labour for a week, and was ultimately delivered with instruments. Her second labour was not nearly so severe. Her third labour occurred in March last. The pains began on the 7th, and were regular, as well as severe, until the 9th, when the child's movements ceased. The pains continued very severe, and on the evening of the 11th instruments were applied. After some hours' exertions, she was delivered of a female child (still-born), which weighed over 12 lb. She was not conscious of passing her urine after the labour was over; and when, a few days afterwards, she arose with the intention of doing so, she found that it all passed involuntarily. A slough came away about the tenth day. She has recovered her general health, but has no control over the bladder in any position.

"May 15th, 1860.—I examined her, and found an opening into the bladder about the size of a shilling. It was situated a little distance from the os uteri, and extended up into the lateral wall of the vagina. There was a constricted band extending across the vagina, and involving the anterior edge of the opening. I placed her on a preparatory course of tonics, and on the 29th of May proceeded to operate, in the presence of Messrs Plumbe (of Maidenhead), G. Brown, Clark, and Philip Harper. She was placed on her hands and knees, and did not take chloroform. In order to obtain a more complete command of the opening, I first passed one of Startin's needles through the edges, and then pared them freely; five sutures with bar clamps were applied. The usual after-treatment was adopted.

"Everything went on well for five days, but on the sixth there was a slight escape of urine. I removed the bar clamps on the tenth day, and found that the greatest portion of the opening had healed, but a small piece where the constricted vaginal band was attached had not done so. As she was extremely anxious to return home, I determined to make another attempt to close the remaining fistula, without previously dividing the band, as I generally do. A fortnight afterwards, I again operated in the same manner, and in the presence of the same gentlemen. The opening this time required only three of my bar clamps. She went on very well this time; and on the eleventh day I removed the clamps, and found the opening perfectly healed. A few days later she returned home.

"*Remarks.*—This case would have healed by first operation if I had previously divided the constricting band, which, by constantly dragging on the inner edge of the fistula at every movement of the patient, disturbed the co-adapted edges. Although two operations were performed, the patient was cured and returned home in five weeks.

"Case 6.—*Large Fistula; two operations; cure.*—(From the reports of the London Surgical Home)—H. S., aged twenty-one, admitted into the London Surgical Home under the care of Mr Baker Brown, May 26th, 1860.

"*History.*—Three years ago she was delivered of her first and only child. She was three days and nights in labour, and was then delivered with instruments. She was very ill afterwards, and about a fortnight later found that her urine escaped per vaginam; this it has done ever since, and she has been in a miserable condition.

"On examination, the vagina was found much cicatrized, and the os uteri protruded at the vulva. The fistula was of the size of a florin, involving half the urethra and a large portion of the bladder.

"May 31st.—Mr Brown divided the constricted bands in the vagina, and plugged the parts with oiled lint. Sponge tents were afterwards applied till

"June 28th.—The parts being now perfectly healed, she was placed on her hands and knees without chloroform. Having passed two long needles through the edges of the opening so as to raise them into view, Mr Brown thoroughly pared and brought them together by seven silver sutures, using no clamps, but simply twisting the wire.

"July 5th.—Sutures removed; all healed except a very small hole about the size of a small pea.

"19th.—Mr Brown operated again, the patient not being under chloroform. He used two bar clamps.

"28th.—Clamps removed; all quite healed. Loses a little urine from the natural passage, from want of power to retain it.

"Aug. 12th.—Discharged, quite cured.

"*Remarks.*—It will be observed that the simple twisted sutures were here used: my reason for doing so was, that, half the urethra having been lost, any button or bar clamp would have pressed on the remaining half and interfered with the free passing of urine.

"Case 7.—*One Fistula; two operations; cure.* —(From the case-book of the London Surgical Home.)—M. B——, aged thirty-two, married, has had one child (still-born); admitted into the London Surgical Home on the 18th July, 1860.

"*History.*—Has been married fifteen months; was confined of her first child April 6th. The labour lasted twenty-four hours; no instruments were used. She was very ill after the labour, and about a week later her urine came away per vaginam; since then she has passed none naturally per urethram.

"On examination, there was found a fistula about an inch long, situated at the junction of the urethra with the bladder. There was also a tight circular mucous band, which constricted the vagina; just above this could be felt the os uteri, which was very low down.

"July 19th.—Mr Brown divided the band, and plugged the vagina with oiled lint, the patient not being under chloroform. Sponge tents were afterwards used until Aug. 2nd, when Mr Brown operated, the patient not being under chloroform. He used three bar clamps.

"Aug. 11th.—Clamps removed. The fistula seemed quite closed; but towards evening the nurse found that there was a slight escape, the united parts having separated.

"16th.—Mr Brown operated again, the patient being under chloroform. Bozeman's button, with six shots, was used.

"27th.—The button was removed, and the whole wound was found to be quite united.

"Sept 8th.—Up to this period she had been gaining strength, and had been out several times. On examination, Mr Brown found that the fistula was quite healed. The patient therefore left the same day for her home.

"*Remarks.*—This is another of those cases where there was a want of power in the parts around the fistula, and where I gave credit for some part of the opening being healed, because it was filled up with loose granulations. It is always, therefore, better to cut away all the parts apparently united by such granulations before operating; yet it will be seen that she was cured in the short space of five weeks."

Dr Richardson contributes to the 'Medical Times and Gazette' a Clinical Lecture on a case of *Phthisis Pulmonalis*, in which amputation of the foot had been performed. We reproduce it:

"In bringing this case before the class, Dr Richardson remarked: You are aware, gentlemen, that during this year we intend to meet every Saturday morning, to conduct a demonstration of disease, either from the living subject, or from some post-mortem specimen derived from a case with the history of which we are familiar. I shall sometimes perform this duty, while at other times it will, I hope, be undertaken by one or other of my colleagues. I shall never come before you with the mere notes of a case ready prepared, simply to read them out; but I shall on every occasion, when we have a patient, take from the patient, as far as he can give it, the history of his case at the time he is before you. You shall hear his own account, and, as we follow out the diagnosis, you shall take down in a note-book, specially retained for this purpose, deliberately and carefully, every fact exactly as I record it in my own journal. Now, the patient before us on the present occasion is a young man, twenty-one years old. He tells us that he is a lever-escapement maker, and has been much confined at his business in-doors; a very important point always to elicit, this one of occupation. He has been ill four years; and we learn from him that his father died from an accident, that his mother is living and well, and that there is no special hereditary taint in his family. His habits have been temperate; his face, you will observe, is expressive of debility, and his body is deficient in flesh.

"On the 21st of November, 1856, having been previously in good health, he was seized with giddiness, while sitting at his work, and fell off his stool insensible. He remained ill with brain

symptoms for fourteen days, but eventually recovered. He took cold a fortnight afterwards, and then commenced to suffer from cough. From this time for twelve months he suffered from hacking cough, which did not keep him from work, but was attended with night perspirations and loss of flesh.

"On the 24th of July, 1857, he got a sprain in the left ankle, and the joint afterwards took to swelling, very slowly, with great pain and hardness. This rendered him more restless and anxious even than the cough.

"On October 16, 1857, he was admitted into St Bartholomew's Hospital, under Mr Lawrence; he remained there nine months, during six of which he was in bed. Within one week after his entrance into the Hospital, hæmoptysis came on and continued at intervals for a month, after which it subsided.

"The foot was first treated by leeching, afterwards by poultices, which were continued for six weeks, and then a point having appeared anteriorly, an incision was made, but nothing followed.

"Internally he had a mixture for his cough, and cod-liver oil, with good diet.

"On three different occasions amputation of the foot was contemplated, but each time the operation was deferred owing to existing disease in the lungs.

"He was discharged at the end of nine months uncured.

"The patient then passed under the treatment of a Homœopathic Practitioner, who put the foot in a heavy iron-splint (which weighed six pounds) with an adjusting screw; by means of the screw attempts were made every fourteen days at extension.

"The joint, during this time, was more enlarged than ever, and presented four open wounds. The main treatment consisted in endeavouring to put the foot straight, the toes being directed somewhat downwards. A liniment was also used for the foot.

"He was subjected to these measures for twelve months, during which time he grew worse: the cough increased, there was more expectoration, the night-sweats were much aggravated, and for many nights he lay entirely sleepless from pain in the joint.

"On November 25, 1859, he was admitted to the Royal Infirmary for Diseases of the Chest, under my care: the cough was then very severe; there were evidences of tubercle in both lungs, and the tubercular crepitation in the apex of the left lung was large and moist. The left ankle was entirely disorganised: on the anterior surface were four deep and wide sinuses, which communicated with the articulation.

"The heavy boot was withdrawn; as much exercise out of doors as possible was ordered; cod-liver oil and one grain of quinine were given three times a day, and five grains of gallic acid with one-third of a grain of morphia every night—with full diet.

"He continued under this treatment until February 1st, 1860, the lung disease not becoming materially worse; but the anxiety from the pain in the foot, together with the discharge, were increased.

"On the 2nd of February, 1860, Mr Wm. Adams saw the case in consultation, and on the 16th he removed the diseased foot by Pirogoff's operation at the Great Northern Hospital. The operation was performed under chloroform.

"At the end of the first fortnight the wound was nearly closed, but there was a little discharge at the side for six months.

"Immediately on the removal of the foot, the chest symptoms, and all the signs of debility, began to improve, and on June 18 an examination of the chest showed dulness on percussion on the left side in the apex of the left lung; but an entire absence of crepitation from both lungs, and of all the acute signs of phthisis. At this date the patient had resumed his old employment, and continued at it until the latter end of September. He could walk on the stump, and do a good day's work.

"At the latter end of September he again began to cough, and on the 18th of October he spat a little blood.

"November 3.—At the present time the condition of the patient is as follows:—The stump is entirely healed, and presents a perfect cushion; he can bear his whole weight upon it without any difficulty or pain: he sleeps well, but perspires at night; there is some emaciation; the conformation of the chest is good, but there is deficiency of respiration on the left side; there is marked dulness on percussion on the left side in the subclavicular region, and also over the lower part of right lung anteriorly; there is further dulness, not so marked, on both sides of the chest posteriorly: on auscultation, there is increased vocal resonance on the left side in the subclavicular region, with deficient respiratory murmur; while lower down, towards the nipple, there is small dry crepitation. There is the same kind of crepitation in the lower anterior portion of the right lung.

"The patient is again taking cod-liver oil, quinine, and the opiate gallic acid pill. Such are the facts,—you will now each one examine the patient for yourselves, as you have seen me examine him.

"*Observations.*—After the examination of the patient by the class, Dr Richardson continued,—Now the great practical interest of the case turns on the question of the influence of the operation that has been performed on the progress of the symptoms. It is quite clear that in this instance the removal of the diseased foot has not only arrested the course of the phthisical affection, but has produced virtually a cure. Was it, then, right in every case so complicated, to remove the offending part? The common view is against operation in such cases; the theory being that the discharge from a diseased structure, such as this man presented in his foot, acts as a derivative, and prevents the progress of the more fatal disease in the lungs. So distinguished a Surgeon and authority as Mr Lawrence, than whom there is no one more practically learned, hesitated, and at length refused to operate in the case in hand. Nevertheless, after two years' further suffering and exhaustion, the operation has been performed successfully, and this is the third example which I have seen of a similar kind.

"I am bound to say, therefore, with great deference, that experience is not altogether against an operation in such examples; for, in the case under discussion, the man would have been dead long since but for the operation. There are two classes of cases in which tubercle may be connected with disease of the joints: in the one class the patient presents evidence of hereditary scrofulous and phthisical taint, and the local manifestations of disease are conjoint indications of constitutional disorder. Whether in this class an operation is really advisable it is difficult to say. But there is a second class, of which the patient whose history has been adduced is a type, in which the development of phthisis occurs purely from confinement in an impure air, and where the disease of a joint is the result of an injury. Here there is no common or constitutional cause for the two disorders; and here, whenever such diagnosis can be determined, the removal of the diseased limb should obviously be the first point of practice, and specially so if it is clear that the limb itself cannot be saved, and if its presence is the cause of constantly exhausting discharge and pain.

"There is another point of practice to be observed. In many cases of death from chloroform the patients have been found after death presenting tubercle of the lungs. This, consequently, caused an anxiety to the operators in the case narrated; but the chloroform was administered without the occurrence of irregularity of the pulse, or other bad sign, and the recovery was rapid after the narcotic was withdrawn.

"Finally, as regards the present recurrence of tuberculosis in the subject of this Lecture, it is to be traced to the same cause as in the preceding attack—namely, to long-continued exposure to an impure air in an occupation for which no active muscular exercise is demanded. If this patient can get the means to live in the fresh air, he will recover; and, indeed, during a short respite from his business, he has already begun to show decisive signs of convalescence."

Mr Hilliard, Instrument Maker to the Glasgow Infirmary, contributes to the same journal some observations on the *Instruments employed in the Operation for the Cure of Vesico-Vaginal Fistula.* As this paper contains diagrams of a series of new instruments invented by Mr Hilliard, and as the paper would not be intelligible without the plates, we must refer the reader to the original article for information. Dr C. W. Turner communicates a paper on *Scarlatina and some of its Sequelæ.* The Author thinks that the poison of scarlatina acts primarily on the brain. He reports a case, and makes the following remarks upon it:

"It is curious to observe the progress of the disease in this case. At the commencement, the brain was relieved by the rash; still the poison remained in the system, and next attacked the glands of the neck: being foiled in that quarter, it seizes the kidneys; they are unable to do their duty of separating the impurities from the blood, and the brain becomes a second time affected, giving rise to a frightful train of symptoms from the poisoned blood circulating through it, and only relieved by the functions of the kidneys being restored. There is every reason to believe that these symptoms are to be ascribed to the presence of urea in the blood, forming uræmic poisoning. Dr C. J. B. Williams mentions that he has known the fluids of ascites and anasarca induced by diseased kidneys to emit a decidedly urinous smell, and to exhibit on analysis appreciable quantities of urea; further, that one of his pupils detected urea in the serum contained in the ventricles of the brain in a case of fatal apoplexy.

"Another case, among others very similar in all respects to the one which I have related, came under my care in the person of a young girl aged eleven. She was the subject of scarlet fever, and here also was a very depressed condition of the vital powers; still she went on tolerably well for about fourteen days, with but little disturbance of the brain; at the expiration of that time the function of the kidneys became almost suspended, the small quantity of urine which passed being of a very red colour, and charged with albumen. Directly upon this, the brain became affected, convulsions, attended with foaming at the mouth, occurred, lasting for many hours, and returning upon several occasions. On the restoration of the secretion of the kidneys, the bad symptoms all disappeared, and the patient is now well. In this case there were ascites and anasarca, and I was astonished at the large amount of fluid ejected from the stomach.

"It appears, then, that in scarlatina the brain may be twice affected: the first attack arises from the direct action of the scarlatinal poisoning upon that organ; the second attack arises from the presence of other poison in the blood, arising from a suspension of the eliminative functions of the kidneys. In the preceding cases the brain attack was dependent on the disordered state of the kidneys. I will now relate a case where the brain was primarily affected and continued the seat of the disease, the kidneys were not concerned in the business at all, and the attack was altogether different from the one which occurs later in the disease: this form I have always observed to simulate, and indeed is, active inflammation of that organ; whereas, the second attack, although exhibiting a fearful train of symptoms, yet the symptoms do not arise from the brain itself, but are dependent and caused by the suspended functions of the kidneys. The present case occurred in a child of my own, who, when attacked with scarlatina, was ten years of age. The symptoms set in most severely, with extreme drowsiness, intense headache, constant sickness, great heat of skin, and a full, quick pulse. The next day, in addition to all the high febrile action and sensorial disturbance, the pupils were contracted, giving the eyes that ferretty appearance so characteristic of phrenitis. The most active remedies were used,—bleeding, leeching, calomel, bladders of ice to the head, blisters, &c. After some days the acute symptoms were removed, but in place of contracted pupil we now had all pupil, and we found that paralysis of the whole left side had taken place. By blistering, placing the system slightly under the influence of mercury, salt water fomentations, and at last cod-liver oil, &c., the use of the side recovered, and she is now a strong, healthy girl of seventeen: the only point remaining of her most formidable attack is that with a difficult piece of music she cannot always

depend upon her left hand. In this case the whole strength of the disease seems to have expended itself in the part first affected: there was no deficiency of renal secretion, no anasarca, but there must have been effusion in the brain. I have notes of other cases, illustrating in a remarkable manner the difference of the brain-attack on the commencement of scarlatina from that which takes place as a sequela of the disease. As, however, the cases which I have related are a type of the others, it will be needless to occupy your valuable space further by citing them. I will conclude by remarking on the difference of scarlatina as existing at different seasons and places. In the autumn of 1858 scarlatina prevailed in another part of this district, and the disease ran its course without any of the usual sequelæ. Evidence, however, presented itself, showing how a very severe attack of scarlatina may result from communication with a mild one. It happened that scarlatina broke out in a school; all the cases did well, and no after-symptoms, in the form of anasarca, &c., ensued. One of the pupils went home, a distance of some miles: he did not take scarlatina himself, but he communicated the disease to his sister, and she died of it. Another pupil went into another county: his mother took the disease from him and died.

"I would mention also another case,—the daughter of a high dignitary in the Church. This young lady was the subject of a most formidable attack of scarlatina, and I doubted her having had the disease before; but her father told me she certainly had,—that he removed her into the country, and on his return he met a friend at the railway-station, and, as they travelled together, he offered him part of his rug: when he met this gentleman some time after, he told him that he had given his daughter scarlet fever.

"The cases referred to in the beginning of this paper occured in April and May of last year."

We continue this week our quotation from Dr Goodfellow's Lectures on *Diseases of the Kidney*, which appeared in the 'Medical Times and Gazette' of the 17th inst.:

"Poiseuille's experiments proved that the mixture of alcohol with the animal fluids, both when directly injected into the blood-vessels, and after being taken into the stomach, retards the circulation through the capillaries, although its first effect is to excite the heart to increased action. It diminishes the want of food, and impairs or destroys the appetite for it. Bouchardat remarks that with drinkers of brandy and other alcoholic liquors, the alcohol acts by diminishing and suppressing probably the functions of absorption by the stomach in respect of every other substance; it augments, on the contrary, the secretion of that organ; and from these conditions arise the increased secretion of mucus, the disgust for food, and the emaciation. Of course such liquids as beer, some wines, and cider, and other nutritious and true alimentary and fattening drinks, are not included.

"That it affects the nervous system, and indirectly, if not directly, the muscular system also, I need scarcely mention; it is too often rendered obvious to us. A moderate quantity produces an excitation of the nervous system, which extends over the whole economy; a still larger dose produces great disturbance of the cerebral functions, which another and still larger dose completely annihilates. The same effects nearly are observed upon the muscular system. A moderate dose seems to impart strength to the muscular contractions, while a very large dose destroys all voluntary contractility, and a poisonous one that also of the involuntary muscles. Flourens' experiments upon the effects of alcohol upon birds are very instructive. Its effect upon them resembled that produced by the removal of the cerebellum, except that the intelligence remained. With alcohol, I need not say it was destroyed. In poisoning by alcohol, the respiratory movements and those of the heart were the last affected,—those of the heart the last. Even for some considerable time after respiration had ceased, the heart continued to beat. In the experiments which I made upon the frog, which some of you witnessed, the heart continued to beat, the circulation went on, for some time after respiration had ceased.

"*Their Pathological Effects.*—That alcohol is a local irritant is unquestionable, and that it produces its effects upon the system partly in this way is very probable. It may act remotely by sympathy to some small extent, as Orfila believed. But we have seen from the very able researches of MM. Lallemand, Perrin, and Duroy, from whose book I have already quoted so largely, that it is rapidly absorbed by the venous radicles, and that its principal action is directly upon the different organs which it irritates, and eventually inflames. Especially has it been proved to be present in greater proportion in the nervous tissue than elsewhere, which it more particularly excites. It disturbs its functions; it perverts and ultimately destroys the intellectual faculties, and even the emotional faculties; it disturbs the function of the sensory nerves, both common and special, as shown by subjective tactile phenomena, strange perversions of taste, double vision, and other disorders of the optic nerves—tinnitus aurium, and other disorders of the auditory nerves. It equally disorders and destroys the function of the motor nerves, as shown in irregularity, and absence of consentaneous action of the movements. From these effects upon the cerebro-spinal system it is more than probable that it disturbs and impairs the functions of the organic nervous system, as evidenced by defective nutrition and secretion. When taken in the form of brandy, whisky, gin, and such fluids, it impairs nutrition, probably from its great attraction for water, inspissating the blood and juices of the body. I need not mention in what large proportion water enters into the composition of the tissues and fluids of the body. It is probably in this way that it acts as a diuretic so far as the increase of the watery part of the urine is concerned, not only from the increased quantity of water ingested with and after the brandy, but from its abstracting it from the tissues. There is no doubt that it tends to harden the brain substance, and produce atrophy of many of the structures, not only by increasing the quantity of connective tissue and other white fibrous tissues, and so leading to undue pressure upon the more important parts, but by condensing the tissues directly by the abstraction of water. There is no doubt of its exerting this destroying influence upon the liver. I shall endeavour to show you that it does so upon the kidney also. As a general rule, it irritates and inflames the tissues of the stomach and duodenum, and even the pancreatic and hepatic ducts; and it probably affects and deteriorates the secretion of these glands. It produces hypertrophy of the connective tissue forming Glisson's capsule, which in its turn presses upon the small vessels, and upon the hepatic cells, and produces atrophy of these anatomical elements in two ways; first, by cutting off the supply of nutrient materials, and secondly, by absorption from pressure. The digestive processes are probably still more impaired by the bad quality of the bile and pancreatic secretion.

"Now, very much the same changes take place in the kidney as in the liver and other organs. We have seen that alcohol passes through the vessels and tissues of this organ as alcohol: it irritates these tissues, as it does similar tissues in other parts; it leads to blood delay; it impairs the influence and function of the nervous system; it produces hypertrophy of the connective tissue, forming the stroma or framework of the organ, and of the capsule; and it produces a granular appearance precisely as it does in the liver. In fact, this alteration is very commonly seen in both these organs in old drunkards, especially and almost exclusively those who take the raw spirit in large quantities, or spirit mixed with only small quantities of water. Those who drink largely of beer, and perhaps of wine, are found to have a somewhat different form of kidney, especially when taken as gin, brandy, &c. But we have seen that alcohol separates and modifies the fatty matters of the blood. MM. Lallemand, Perrin, and Duroy have seen this. Most pathologists believed that so far as the relation between cause and effect could be traced, it was almost certain that alcoholic beverages, when largely and continuously consumed for any length of time, led to fatty degradation. This separation has now been actually seen and proved. Now, this separation and alteration of the fatty principles of the blood probably plays a very important part in the pathological effect of alcohol, when taken in large quantities, in the form of brandy, gin, whisky, &c. Now, saponifiable fatty matters, that are visible to the naked eye, are calculated to impede the circulation through the capillaries,—if not cut off the blood supply altogether,—and so produce atrophy of the secreting tissues, while the connective tissue, supporting the vessels, would receive an undue supply of blood plasma, and therefore become hypertrophied. It is not improbable that some of these fatty matters become transuded with the exudates, and thus lead to the presence of fat in the tubules, and also in the intertubular substance; some may also remain in the walls of the capillary vessels, and replace in time the normal elements. We had a case in Cambridge Ward in the summer, which most of you witnessed, and which offers a striking example of this, for large fatty particles could be seen by the naked eye floating upon the surface of the blood. This man, whose name was Beck, was admitted on the 25th of May. On his admission he was considered almost moribund. The dyspnœa was extreme, and so was the anasarca. There was evidence of enlarged heart, and of extreme œdema of the lungs, and of effusion into the left pleural cavity. Many of you will recollect the opinion I gave as to the nature of the changes that we should find in the kidney. According to his own confession, he had drunk immensely, principally of gin; but he was not at all particular. He was a musician, and in the habit of playing at dancing parties; but he was always well off, lived well, and except at times, when he was more drunk than usual, he was not liable to exposure to cold. He had had eleven children, but they all died in infancy or early childhood. From the cause alone in this case, you will recollect that I ventured to state what would be the condition of the kidney after death. At that time we did not expect that he would live many days. He, however, rallied for a time, but died eventually on the 29th of the following month, the immediate cause of death being an attack of bronchitis. During his stay in the hospital, we had opportunities of confirming the diagnosis by the examination of his urine, and the general symptoms and signs. I told you that the kidneys would probably not be enlarged, and that they would not vary much from the normal weight. I stated that they would be found to be extensively granular, that there would be numerous small cysts, that the cortical portion would be much reduced in thickness, and that there would be a considerable quantity of fatty matters. This turned out to be an accurate description in every respect. Although this man was a drunkard by his own confession, yet it was impossible to see much of him without being convinced that we had got the whole truth from him. You will recollect how he won the regard of all who watched his case, from the patience with which he bore his great sufferings, and the intelligence and other good qualities which he evinced. There were several other circumstances of interest connected with the diagnosis in this case, but as I only quote it for the purpose of alluding to the spirit kidney I do not think it necessary to speak of them now. In persons who become the subjects of kidney disease from the excessive consumption of beer, another form of kidney is found. Instead of the small granular kidney, with its cortical portion diminished at the expense of the medullary portion, it is generally a mixed kidney, something between the large white kidney which we see after scarlatina, and the true granular kidney with more or less of fatty deposit, both in the tubes and in the interstitial tissue.

"Never overlook, in seeking for the mode of causation of these diseases, the great influence of the sympathetic nerves—the greater and lesser splanchnic, and even of the par-vagum—upon the secretion; and, if any cause is in operation to interfere with the function of these nerves, how the circulation of the organ is necessarily affected, and therefore its secretion also. I have now given three of the most important causes; I may say, perfect types of their respective kinds. One, namely, scarlatina, is an example of our first category,—those whose action is upon the blood primarily, and upon the nervous system, and the tissues of the organ, secondarily; another, namely cold, is an instance coming under our second category,—those which affect the nervous system primarily, and the blood and tissues secondarily; and thirdly, alcohol and its allied compounds, which may fairly be said to partake of the characters of both these modes of action, indeed of all three. Perhaps with strictness it ought to be placed under our second heading.

"It now only remains for me to give you an example under our third class—those which, either by direct or reflex action, affect the tissues of the organ primarily, and its own nerves secondarily.

"The key to the action of these causes is to be found, I take it, in these quotations from M. Claude Bernard:—"Albumen is constantly in the urine, and the tissues of the organ; and its blood-vessels become turgid and black, every time that we irritate the substance of the kidney. If, leaving the organ intact, we even irritate its nerves, the same effects ensue.' 'If the function of the nerves be suspended, temporarily or permanently, the secretion of the kidney will be arrested, and the circulation also, and the organ will be rapidly destroyed.' Consider the effects of such direct irritants, both upon the nerves and structures of the organ, as alcohol, turpentine, and cantharides, in connection with these results of experiments performed by M. Claude Bernard, and you can have no difficulty in understanding their mode of action in the production of these kidney diseases.

"The same may be said of those disordered states which act by producing reflex irritation: calculi in the pelvis of the kidney, the ureter, or the bladder; catarrhal affections, gonorrhœa and so on, dysmenorrhœa, and even Onanism and excessive venery.

"You are aware that the renal plexus is chiefly formed by the solar plexus and the lesser splanchnic nerves, and that the renal plexus gives branches to the spermatic plexus: hence the morbid sympathies which exist between the kidney, the ureter, and the testicle; and, by the communications with the solar plexus, with the stomach and diaphragm, and, indeed, with the whole system. You will not fail to perceive, then, how any irritation in the ureter, the testis, the uterus, &c., is calculated to give rise to reflex irritation in the kidney, and *vice versâ*.

"In the next Lecture, I shall give a cursory review of the several forms of kidney, the result of one or other of the several affections coming under the general denomination of Bright's Disease."

The 'Dublin Medical Press' contains a report of *Two Cases of Aneurism of the Thoracic Aorta*, by Dr G. W. Egan, occurring in the practice of Dr Geoghegan and Dr Benson.

"Case. 1.

"John A——, ætat. forty-six, an iron-worker, admitted June 18, 1860.

"*History.*—The patient had previously in general enjoyed good health, but his habits were intemperate. About six months ago he became affected with pains in the back and shoulders, and with hoarseness almost verging on aphonia, which he attributes to the influence of cold: a fresh exposure about a fortnight before admission was followed by increase of the last-named symptom.

"*State on Admission.*—The face is florid, injected, and anxious; the lower part of neck very full, as if swollen, the trachea lying at a great depth: there are present, aphonia; hoarse, stridulous, and somewhat difficult inspiration; uneasiness referred to the *pomum Adami*; occasional cough, the sound of which very strikingly resembled the *yelp of a dog*; and an inability to snuff up air suddenly through the nostrils when the mouth is closed. Articulation is performed in a hoarse and gasping whisper. Some bronchitis is also present, accompanied by attacks of spasmodic difficulty of breathing, chiefly laryngeal. Physical examination of the chest revealed marked dulness along the sternum and beneath the inner third of the left clavicle, extending downwards for a distance of about two inches. In this situation a distinct double sound and impulse were observed, both being respectively much louder and more forcible than those of the heart, which were audible in their usual place. The first of the above sounds was accompanied by a short *bruit de soufflet*. The heart-sounds were somewhat feebler, perhaps, than natural: no difference was perceptible in the respiratory murmur beneath the clavicles, and the outline of the anterior wall of the chest appeared unaltered. Both lungs were pervaded by slight sonorous râles. The pulse in right radial artery was much stronger than that in the left; in the left carotid it was extremely feeble. There was a loud, rough, tracheal sound in windpipe; no dysphagia was observed.

"*Diagnosis.*—Aneurism of the arch of the aorta, complicated possibly by antecedent slight chronic laryngitis; the present exacerbation appeared chiefly due to bronchitis, and the remedial measures were directed accordingly.

"*Progress and Treatment.*—After the patient had been in hospital a few days, sudden paroxysms of suffocation referred to the larynx occurred every evening, and were at first abated by tartar emetic and opium. On the fifth day after admission he was seized with an attack of so urgent and formidable a nature, that, to avert *immediate death*, Dr Geoghegan performed laryngotomy by plunging a scalpel at once into the crico-thyroid space, and introduced a canula into the opening. This measure was speedily succeeded by quiet and regular breathing (28 in the minute). The temperaure of the room was ordered to be suitably maintained. Occasional slighter recurrences of difficult breathing were at once relieved by removal of mucus through the canula. Notwithstanding, however, the adoption of these and other necessary means, the patient gradually became collapsed, and died eight hours after the operation, having remained apparently unconscious and as if sleeping up to the period of his decease.

"*Autopsy, eighteen hours after Death.*—The heart was enlarged, and presented a good deal of fat on its surface. The right ventricle contained a considerable fibrinous clot, extending into the pulmonary artery; the right auricle, a similar one, together with dark coagulated blood; the left auricle, a dark coagulum; the left ventricle, a small fibrinous clot. The valves of the organ were healthy.

"The ascending aorta was much dilated, and near the heart was beset with calcareous plates, and elsewhere with atheromatous patches, in which were exhibited, under the microscope, abundant rhomboids of cholesterine. The transverse portion of the arch presented a shallow cavity lined with dark-coloured fibrine, and resting on the tracheal bifurcation: this cavity communicated with the aorta by an opening as large as a crown-piece, the edges being rounded and obtuse. The rings of the air-tube at the seat of contact were partially eroded, so that but a thin septum was interposed. From the upper and left side of the aneurismal sac there was a slight offset or projection pointing towards the sterno-clavicular articulation. The left carotid was about two-thirds the diameter of the right, but pervious; its opening into the aorta was extremely small. The left recurrent nerve was adherent to and firmly imbedded in the parietes of the aneurism; it was atrophied, and its neurilemma injected.

"The left posterior crico-arytenoid muscle was much atrophied, being of a tawny colour, and contrasted strongly in bulk and colour with the right: the other laryngeal muscles on the *same side* were atrophied, but much less so; the left crico-thyroid and all the laryngeal muscles of the opposite side were unchanged.

"The mucous membrane lining the cricoid cartilage was pink, and both here and elsewhere slightly spongy, but not decidedly thickened; the chordæ vocales and laryngeal ventricles natural, with the exception of a lining of viscid mucus. There was universal redness of the mucous membrane of the trachea and bronchial passages, and the tissue of the lungs was congested.

"*Comments.*—In commenting upon this case to the class, Dr Geoghegan remarked that the history, together with the appearances on dissection, rendered it doubtful whether, in the present instance, the whole of the laryngeal phenomena were referrible to the aneurism, as they commonly are, and not in part to pre-existent chronic laryngitis of a mild form. The urgent fits of dyspnœa appeared due to the access of inflammation of the mucous membrane of the trachea and bronchi creating sympathetic spasm in the laryngeal muscles, whose physiological equilibrium was already seriously disturbed by the condition of the left recurrent nerve, the laryngeal.

"The singular yelping sound of the cough, which had been observed previously to the supervention of the attacks of dyspnœa, was clearly due to the influence of the aneurism of the recurrent. Dr G. commented on the condition of the laryngeal muscles, in the present instance, as affording a remarkable example of the practical bearing of physiology on pathology and practice, and stated that the merit of having first drawn attention to the subject was due to Professor Banks of this city, who has figured the state of parts from an excellent and faithful dissection.

"Dr Geoghegan also drew attention to the phenomena of the double sound and impulse, so well marked in the present case, and this although the aneurism (engrafted in a larger dilatation of the vessel) was small and shallow, and had not eroded the anterior wall of the chest. No altogether satisfactory explanation of the above conditions had as yet been offered. The view propounded by that admirable observer, the late Dr Bellingham, refers the first sound and impulse respectively to the friction of the blood against the contour of the opening of the sac, and to the distension of the tumour during the ventricular systole. This view being in harmony with facts, and being sustained by analogy, appears quite admissible. The mechanism of the second sound and impulse seems by no means so clear. Dr Bellingham considers these latter to be the effect of regurgitation from the aorta (and in some cases from its tributaries), under the influence of gravity during the heart's diastole. This doctrine is open to the objection, not alone of being unsustained by any positive evidence, but is also opposed by the circumstance of the persistence of the sound and impulse under conditions in which gravity in the required direction is inoperative or nearly so—namely, in the recumbent posture.

"In the absence of any unimpeachable theory, Dr G. surmised, that the *second* sound and impulse might be due—the former, to the *expulsion* in some cases of a volume of blood from the sac; in others, to its *entrance* of that fluid into the latter (according to the position of the aneurism with respect to the aorta); such entrance or expulsion being effected by the elastic reaction of the cellular wall of the sac, and also by that of the closely adjacent bronchial bifurcation and summit of the lungs. The systole of that portion of the aorta immediately to the distal side of the aneurism may, possibly, in some cases, contribute to the production of the second impulse, by assisting the reaction of the above-named parts.

"The greater strength and elasticity of the coats of the tumour when it involves the arch of the aorta, and especially in aneurisms like the present, of a mixed kind—perhaps also difference in the size of the aperture leading into the sac, may to some extent explain the frequent occurrence of double sound and impulse in the thoracic, as contrasted with the single ones which are usual in other parts of the arterial system.

"In the present case the operation of laryngotomy was merely resorted to in the discharge of the duty of prolonging life, as suffocation was absolutely imminent. In such a case as the present, and in various other emergencies calling for an immediate opening in the air-tube, it appeared to Dr G. that laryngotomy fulfilled all the necessary indications for the supply of air, the obstruction being seated above the artificial opening, whilst the rapidity and safety with which this operation can be executed in a case where promptitude is everything give it here a decided superiority over tracheotomy: had the latter procedure been attempted in this instance, great difficulty, and perhaps fatal delay, must have ensued from the depth of the lower part of the neck, and also serious risk from the close proximity of the aneurism to the trachea. Dr Geoghegan also remarked that in the extraction of foreign bodies from the larynx in children, additional room may be gained by prolonging the incision in the crico-thyroid space downwards through the median line of the cricoid cartilage; the isthmus of the thyroid gland, if divided, either not yielding any hæmorrhage, or the latter being quite readily controlled. Dr G. had employed this manœuvre in one instance with complete success: the elasticity of the cricoid cartilage, especially in the young, allowa the edges of the incision in it to be divaricated to a very notable degree without injury.

"The attention of the class was also drawn to the necessity for employing a suitably fitting canula in performing laryngotomy, with a view of preventing the trickling of blood into the windpipe from the divided laryngeal branch of the superior thyroid.

"In this case death seemed most probably due to modified or syncopal asphyxia. The repeated severe attacks of laryngeal spasm, aided perhaps by a partial extension of the bronchitis to the capillary tubes, had interfered materially with the arterializing process. The final symptoms, however, together with the state of the heart cavities, indicated a concurrent but independent condition of progressive syncope. Had bronchitis been absent, the patient would probably have survived until the aneurism had burst into the trachea. The relief which immediately followed the operation was decisive. In a case similar to the present, Dr Beglie had recourse to tracheotomy with similar temporary advantage."

To be Continued

The 'Dublin Hospital Gazette' contains a Translation from the 'Hospitals-Titende,' by Dr Moore, of a Report of a Case of *Fibrous Polypus of the Base of the Skull*, extirpated by resection of the upper jaw, in the Surgical Department of Frederik's Hospital, Copenhagen. We omit the preliminary matter, and quote the case:

"Hans Rasmussen, aged eighteen, a servant-boy from the country, was admitted into Frederiks Hospital on the 19th of June, 1859. The patient, who as a child had not been scrofulous, and, with the exception of the usual diseases of childhood, had not suffered from any illness, began four years ago to observe some obstruction in the left nasal cavity, with purulent discharge and frequent bleeding. He applied to a surgeon, who, according to his statement, extracted a polypus from his nose, after which he felt well for six months; but three years since, obstruction to the passage of air through the nose again occurred, with purulent discharge and hæmorrhage in a still higher degree than before, and about the same time the patient experienced a feeling of tension and incipient tumefaction of

the left cheek, which gradually swelled up to the size it now presents. A year and a half ago, he began to have piercing pains in the left orbit, while at the same time the sight of the left eye was weakened. Shortly after, he observed the eye becoming more and more prominent, and the pains, which gradually increased, extended over the whole head, assumed a more palpitating character, and sometimes occurred in such violent paroxysms that he was almost deprived of self-possession. The sight of the left eye progressively decreased, without any accompanying symptom, to such a degree that for the last three months the patient has been quite unable to see with it. For the last half-year he has also usually had flying pains in the left cheek, and in the molar teeth of the under jaw on the same side. He has, besides, been rather deaf, and complains of constant singing in the left ear, and of severe throbbing pain in the right. He speaks with a thick, snuffling voice, but has no particular difficulty in swallowing. He suffers somewhat from a defluxion in the pharynx, from the posterior openings of the nose, of a fœtid, sanguineo-purulent fluid, which is not, however, discharged so abundantly in this way as it formerly was through the left nostril.

"On examination, no particular abnormity in the shape of the nose nor any external swelling is found; the organ is rather flattened, and in its left half is slightly extended in width. The left nostril is more dilated than the right, and the septum nasi is completely driven over to the right side. Through the left nostril there is seen, about half an inch from the orifice, a roundish tumour entirely filling up the left nasal cavity. The tumour is not sensitive, but bleeds rather easily when touched; it is of firm consistence, and of a bluish-red colour; a sound can easily be passed on the inner side of the tumour, between it and the septum nasi down into the pharynx; but when introduced on its outer side, it immediately meets with resistance to its further progress.

"Through the mouth, the left half of the soft palate is observed to be convex, without any discolouration of the mucous membrane; and the posterior part of the hard palate is somewhat depressed, but without any perceptible attenuation of the bony substance. The finger, when introduced, does not detect any considerable swelling behind the velum palati. The teeth are all uninjured. The left cheek, on the contrary, is seen to be much swollen, and both externally and internally a roundish, somewhat flattened, soft, and painless tumour can be felt, apparently proceeding from the superior maxillary bone, close under the zygomatic arch, and hanging a couple of inches down, occupying the part between the otherwise healthy skin of the cheek and the mucous lining of the latter. No swollen glands are discoverable in the sub-maxillary region, nor is anything abnormal found in the ear externally.

"The left eye is seen to project considerably, so that the eyelids can scarcely close; the sight of this eye is completely lost, without anything morbid being perceptible on external inspection; the pupil is not dilated, and the iris moves freely. The patient at present suffers no pain; his general health is good.

"22nd.—This day the patient had a paroxysm of ague, with violent rigor. The same recurring on the 26th, ten grains of sulphate of quina, in four ounces of acid mixture, were prescribed. The paroxysm again recurring on the 29th, the quina mixture was repeated, since which time there has been no relapse. On the 8th of July he was operated on, while under the influence of chloroform.

"The nose and upper lip were divided by a longitudinal incision along the middle line from the root of the nose, where the longitudinal incision was united with a transverse cut, passing to the inner canthus of the left eye; the left lower eyelid was set free by cutting through the mucous membrane, and the entire quadrangular flap of skin, together with the soft parts covering the left half of the nose and the left superior maxillary bone, were turned aside. By means of a bone-nippers and a chisel, the greater part of the superior maxillary bone on the same side was taken away, together with a portion of the zygoma, leaving only the floor of the orbit above, and the alveolar process below.

"The antrum highmorianum was found empty and greatly compressed. On removing the above-mentioned portion of bone, the part of the polypus lying externally to the superior maxilla could be traced up under the anterior part of the zygomatic arch into the spheno-maxillary fossa, where it was connected by a slender arched portion with another production of the same size, which, in front of the pterygoid process, and perforating the upper part of the palatine bone, extended through the left posterior naris into the left nasal cavity, wholly filling up the latter. These two productions, which thus together formed a half arch, had on the middle of the convexity of the arch a roundish, hard stalk, one inch in length, and three-quarters of an inch in thickness, attached to the periosteum on the anterior portion of the basilar part of the occipital bone, and the inferior surface of the body of the sphenoid bone, where the osseous wall was so softened, that after the removal of the tumour, one easily penetrated into the cavity of the sphenoidal sinuses.

"When the polypus thus lay exposed, with its two boundaries, in the bottom of the region, the production was first dissected which lay upon the superior maxilla, and had strong adhesions to the periosteum of all the osseous parts bounding the spheno-maxillary fossa. The formation lying in the nose was then also separated; it was tolerably firmly adherent to the posterior part of the septum nasi. Both productions were thereupon taken out connected, by dividing the stalk behind them with a curved nippers, and the stem itself was subsequently separated from its strong adhesions to the roof of the pharynx.

"After the removal of the polypus, the actual cautery was strongly applied to the seat of insertion, the flap of skin was then replaced, and the edges of the wound were united by suture. Considerable hæmorrhage attended the operation, which lasted three-quarters of an hour, and towards the close the patient had become very anæmic, so that the radial pulse could no longer be felt. Port wine was therefore given.

"9th.—The patient yesterday several times evacuated some black blood by vomiting and per anum. He has, however, recovered his strength very well, and is more lively. The pulse is tolerably full—120.

"12th.—He is much troubled with fœtid breath, caused by the wound in the pharynx. Gargle of tincture of myrrh. The sutures were removed, and adhesive plaster applied. Constant injection with water.

"14th.—He got up.

"15th.—The wounds are, for the most part, healed. The patient's general state is satisfactory.

21st.—He is beginning to see slightly with the left eye, which was previously blind. The prominence of the organ has ceased.

"August 1.—The discharge from the nose is trifling; the patient's general state is very good. He was out for an airing.

"3rd. The power of vision of the left eye is steadily increasing, so that he can now discern the outlines of large objects. On the left cheek, where the outer extremity of the polypus was dissected away, was a little abscess, which was opened.

"8th. The patient looks well; his nose is a little flattened on the left side, but the obliquity is slight.

"14th. The sight is still misty. The patient was discharged at his own request.

"On reviewing the foregoing case, it is evident that in one principal point the extirpated polypus is referrible to the category of those described by Nélaton. Thus the morbid growth proceeded entirely and distinctly from the base of the skull, and had a tolerably defined insertion into the body of the sphenoid bone, and the anterior portion of the basilar part of the occipital bone. It here had a firm and solid adhesion, but was without difficulty removed by means of the curved scissors, and was therefore not possessed of the degree of solidity met with by Jarjavay, and which resisted even the scisssors. It appeared, however, as others also have observed, that the surface of bone on which it sat was so attenuated and changed at the attachment of the tumour, that it was perforated on the application of the hot iron, so that the latter seemed to penetrate into the interior of the bone, probably into the sphenoidal cells. On the other side, there were also strong adhesions to other surfaces of bone—to the septum nasi, to the zygomatic fossa; but these appear to have been removed with still greater ease, and were therefore probably, as Nélaton has stated, secondary and accidental. This is a main point, which it is interesting to establish, and which is confirmed by the great majority of the cases of this kind latterly published; almost in every instance we trace their origin to the dense fibrous tissue investing this portion of bone. Some writers have, however, observed the origin lying more to the side in the pterygoid fossa, and proceeding from the ala interna of the pterygoid process. Huguier has met with a very peculiar origin—namely, from the fibrous tissue filling the foramen lacerum, the polypus prolonging itself into the dura matter, with which it was in immediate contact. A very few observations are, indeed, found to differ in this respect; thus one is related by Dieulafoy, of Toulouse, where the polypus is said to have proceeded from the antrum highmorianum, and to have thence extended inwards, becoming naso-pharyngeal. But as there are very many examples of the opposite — namely, where the naso-pharyngeal polypus has prolonged itself into the antrum, and even through this sinus, opening a way through the bone into the canine fossa,—it is rather doubtful whether the observation alluded to was accurate; thus the Author states only that seizing it with Muzeux's forceps, he tore away the fibrous polypus and drew it entirely out, through the antrum highmorianum. It is, moreover, by no means constant that the origin of the polypus has with any accuracy been established during operation, as was perfectly done in our case.

"The polypus operated on in this instance was fibrous, of a uniform, filamentous, hard and tough, whitish-yellow tissue. Its form was tolerably regular, representing an inverted T, the descending vertical petiolus being attached to the middle of a curve whose two transverse branches were about equally long, and were rounded and thickened at the ends. These two transverse lateral branches were so situated that the one passed into the left nostril, and so ran in front; the other passed out through the foramen spheno-palatinum into the zygomatic and spheno-maxillary fossæ, and therefore ran outwards to the side. On the contrary, the polypus did not sink down into the pharynx, which would evidently have been the best place for its development, and it was so far not properly pharyngeal: it will be recollected that it was not reached by passing the finger up behind the velum palati. Our polypus was therefore rather regular in its form, thus differing from various earlier ones observed by others, which are correctly called multiple polypi; such have, that is to say, been developed in the nose, as well as in the pharynx, month, antrum highmorianum, and in the zygomatic and temporal fossæ. Nor had this polypus grown to any very considerable size; it certainly produced a strong and disorganizing pressure, to which the amaurosis testified, as well as the fact that the whole of the left of the alveolar arch and the hard palate on that side were slightly dislocated and depressed; nevertheless, the dislocation and diastasis were not so great as others seem to have found them, although these fibrous polypi among the bones of the face scarcely ever attain to any extraordinary size. One observed by Richard and Robert had, however, sunk so far down that it produced difficulty of breathing; and another described by Maisonneuve had developed itself considerably after having pressed forward into the zygomatic and temporal regions, where it may certainly be considered as lying free under the skin, as it sinks down into the connective tissue of the cheek."

(Continued at Page 362.)

APERIENTS IN ACUTE DYSENTERY.

We find in the 'Gazette Médicale de Lyon' a paper by Dr Vernay, Physician of the Hôtel-Dieu of that city, on the exhibition of aperients in acute dysentery. After carefully describing the acute, adynamic, and chronic forms of the disease, the Author represents as follows the course of treatment which he has found most promptly and completely beneficial in cases of less than one month's duration, when the daily evacuations varied from 20 to 100.

On the first and second days he prescribed, for each day, a bottle of Seidlitz water, and twenty drops of laudanum at night.

On the third day the patient took no medicine. In mild cases but two motions occurred at this period. On the next, soup was allowed, and a moderate allowance of solid food on the fifth day; from the seventh to the tenth he was permitted out-of-door exercise. After the aperient, laudanum was found serviceable, but not when prescribed alone. In cases considered severe, in which even abundant motions were observed daily, ten evacuations at most occurred on the third day, and the tenesmus was much less distressing. M. Vernay concluded the treatment by exhibiting on the third, and sometimes also on the sixth day, the following aperient mixture:

℞—Fruct. tamarindi . . ½ oz.
Rhei . . . . . 1½ dr.
Boil in 12oz. of water, and add
Mannæ lachrym. . . 1 oz. Strain.

This formula, which belongs to Sydenham, was found appropriate to this stage. In the incipient period it would have been insufficient to relieve the bowels. After the Seidlitz, however, the tonic and aperient action of the rhubarb proved beneficial.

On the seventh day, two evacuations only occurred. Soup was allowed, and next day light food: the patients were discharged from the twelfth to the fifteenth day. These results were invariably attained when the disease had lasted less than a week before treatment.

With regard to the selection of the aperient, M. Vernay remarks that Seidlitz water or tamarinds are most advantageous at first, and subsequently the rhubarb. The latter drug should, on the contrary, be prescribed at once when dysentery has lasted more than ten days, and is also preferable for the aged and the debilitated.—'Journal of Practical Medicine and Surgery.'

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Untamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

WEDNESDAY, NOVEMBER 28, 1860.

HOMŒOPATHY, HYDROPATHY, AND MESMERISM

IN RELATION TO THE SCIENCE OF MEDICINE.

The transition-state in which the Profession of Medicine is generally admitted to be, formed the subject of an article in our last number. Not only, however, in the relations then delineated, but in many others, is this process of transformation in progress. The rivalries between our numerous Collegiate bodies show the fermentative actions that are at work among them, and the subtle affinities by which the elements are slowly entering into new combinations. The spirit of change is brooding over us, and old forms and usages are undergoing solution and precipitation in the alembic of opinion and controversy. In this general transformation, how does it stand with the principles and the practice of Medicine?

In these respects, too, new ideas are thrown into the cauldron, to sublimate, as it may happen, as a potent spirit, or subside into a *caput mortuum*. What is inflammation? What is tubercle? What is nerve-force? what vital force? What is the mode of action of oily materials in the nutritive processes? What of alcohol? Is stimulation beneficial in fevers and inflammations, or the reverse? Is it possible to trace every disease to a specific cause? Can we artificially or synthetically induce disease, and lay down incontrovertible principles of cure? These questions, and many more than these, are undergoing a patient examination, with the hope of eliminating some potential truths that shall extend the limits of the remedial powers of our art, and enlarge the resources of human longevity and happiness.

Other questions also arise in connection with the various pseudo-remedial systems which have fastened parasitically during the last quarter of a century upon the Science of Medicine. What has been the influence of Hydropathy, Homœopathy, Mesmerism, Chrono-thermalism, and the numerous subordinate branches that have sprouted from these parent stems? We are not in the habit of touching these subjects, because we have too confident a faith in the immutability of the general principles of the science, and too strong a reliance in its steady progress, to fear the disturbing influence of crude and partial hypotheses, which are merely the toys of the learned and the marsh lights of enthusiasts and dupes. We leave to others the congenial duty of knocking to and fro the shuttlecock of opinion and scoring unprofitable victories.

These great heresies, however, have attained so great a prevalence in society, and have enlisted so many votaries from our own ranks, that it would be mere affectation to ignore their existence. Let us ask ourselves, then, what has been their effect upon the science and practice of Medicine?

The advocates of Homœopathy boast that Hahnemann evoked a new principle out of the chaos of Medical doctrine, and established a starting-point for a more harmonious and complete system of Medical practice. Some of his followers, however, assert contrariwise, that he rediscovered the lost principles of Hippocrates, and that he is entitled to be regarded as the second founder of Physic. These, however contradictory, are sublime pretensions; and as pretensions let them stand. Whether Hahnemann be the opponent or disciple of Hippocrates is immaterial; the influence of his doctrines is what we intend to consider.

In one and the main respect, Homœopathy has egregiously failed; the doctrine that "like cures like" not having made the least impression upon the minds of men who cultivate Medicine as a science; and it remains a theory alone among the majority of Hahnemann's followers. The parallelism is, indeed, partially admitted, as it always has been; but the elevation of a few superficial resemblances or parallelisms into the universality of a principle has been decisively rejected. This notion of Hahnemann's necessarily involved a second principle,—that of infinitesimal dilutions; inasmuch as common experience showed that drugs in the ordinary doses produce results, in nearly all cases, just the opposite of those induced by the diseases they are prescribed to cure. This obvious and practical refutation of the principle could be evaded only by such a minute dilution of medicines, that they should cease to have any visible effect. Thus was constituted a second cardinal therapeutic principle, which has now, however, no place even in the Homœopathic creed. The best Homœopathic authors avoid the subject, or advert to it only to characterise it as one of the delusions of a great man; an ungrateful way of picking out one of the eyes of their idol.

It was necessary, in fact, in order that Homœopathy should continue to exist, that this doctrine of infinitesimal dilutions should be abandoned; because it implied to the understanding and conscience of every man who was not a belated enthusiast, that Medicine was not necessary to the cure of disease. Here, indeed, we touch the practical point, and we ask again, what has been the influence of Homœopathy upon the practice of Medicine?

The answer to this question, no doubt, must be, that it has tended to repress the ancient drugging system which flourished in this country during the by-gone Apothecary *régime;* and that the comparisons that have been instituted between the Homœopathic system and the ordinary system as practised in the great Hospitals of Europe have induced thoughtful men to consider more carefully into the ways and powers of Nature in the relief of bodily maladies. All, therefore, that can be said of the real influence of Homœopathy on our science is this—that it has revived in many minds a faith in the *vis medicatrix naturæ*—a phrase that had become a proverb, and a principle that was already formulated into a law, many centuries before Hahnemann was born into the world. Neither the phrase nor the principle, however, was Hahnemann's. Whilst snapping at shadows, he dropped the substance: but he dropped it, we may add, because he did not comprehend its value. Out of his errors, however, we extract fresh testimony to the truth of this perpetual law.

What Hahnemann could not do, what he never pretended to do, and what has not yet been done in a detailed manner, is to determine with accuracy the mode adopted by Nature in relieving herself at the different stages in the progress of disease. When we have become perfect masters of her secret ways, we shall be better able than we are now to counteract her wanderings, and help her in her reactions. The cure of disease can only be effected by the correction or sustainment of certain physical actions and processes: it is necessary, therefore, to the determination of a philosophical method of treatment, that these should be known. We cannot define the limit between morbid and curative processes, for they are obedient to the same law, and the morbid action may, and commonly is, at the same moment a mode of cure. This looks like a paradox; but let us consider. The ulceration of the skin consequent upon a subjacent collection of pus is a morbid process; but, nevertheless, the process is curative, and a good Surgeon imitates Nature and anticipates her ways by an artificial incision into the abscess. We cannot follow up this branch of the subject.

Hydropathy, again, has taught us nothing in the principles of treatment that was not already known; but it has had the effect of calling attention to the advantages of bathing as a domestic institution, and of the necessity also of studying the operation of natural agencies on the system. The science and therapeutics of disease remain, however, unaffected by hydropathic pretensions.

Mesmerism, with all its absurdities, extravagances, and frauds—its spiritual rappings, its

table-turnings, and clairvoyance—has nevertheless quickened a spirit of inquiry into the nature of the relation between mind and body; and, most undoubtedly, an advance has been made by such men as Braid and Carpenter in our knowledge of these psychological phenomena. The wheat has been winnowed from the chaff, and we know the full extent to which Hypnotism can be made available in our art. That extent is limited. That operations have been performed under the influence of Mesmerism is now, we think, well established; but it is a capricious agent, operative only on certain constitutions, and is superseded in utility by chloroform; so that the spiritual agent as a practical resource can never be made generally available.

We need not dilate. These heresies have thrown no new light upon Medical Science, nor provided us with one useful practical agent that was not heretofore known, and Medicine must continue her course of improvement under the guidance of those thoughtful minds and in the direction of those patient labours that have conducted her to her present unexampled altitude and development.

Extravagant novelties, singular hypotheses, premature and vague generalisations, empirical dogmas, will never benefit our art in any important degree. The temple of Esculapius is not an unsubstantial phantom, framed by a fantastic imagination from the vapours of cloud-land; but a solid fabric, erected brick by brick by the persevering and modest labours of the regular workmen whom science has engaged and trained in her service.

SUMMARY OF THE WEEK.

ELLIS *v.* KELLY.

The opinions expressed by this Journal on the Title Clauses of the Medical Act, when that Act was first passed, and since that time frequently repeated, receive confirmation from every new decision on the disputed questions in our Courts of Law. Much money might have been saved, and much acrimonious feeling prevented, if the Profession had been content to put a literal construction on the doubtful phrases, instead of endeavouring to torture them into a sense that they would not bear, and that could not be sustained in one of Her Majesty's Courts. We have always maintained, in opposition to the opinion of our contemporaries, that there is no prohibition in the Medical Act against any "registered" Practitioner styling himself "Doctor" if he pleased; the fact of registration exonerating him from any penalties which might possibly otherwise apply to a usurpation of that title.

The point with us has not been, what *ought* to be the law, or what were the intentions of the promoters of the Bill—though, perhaps, in this respect we are better informed than most men who pretend to know the secrets of the Government and Legislature—but it has been simply, what is the literal interpretation of the Act? The Act does not require—and we repeat it for the fiftieth time—that an individual should be registered under a particular designation, to entitle him to use that designation on his card or brass-plate; nor, on the other hand, does it fix any penalties upon him for using any designation which does not appear against his name in the 'Register.'

The case of Ellis *v.* Kelly, tried recently in the Court of Exchequer, has for ever settled the construction of the Title Clauses of the Act so far as they relate to this question. Dr Kelly possesses, it appears, an Erlangen degree, but it was not entered on the 'Register.' Nevertheless, he continued to style himself "Doctor," for which alleged offence an information was laid against him by Mr Ellis. In summing up the case, the Lord Chief Baron said: "If a man is registered, he may call himself what he pleases." This is a positive opinion; which is not invalidated by the circumstance of the Chief Baron having made, in our judgment, two or three mistakes on points not immediately in connection with the question. For example, he said—if our report, which is taken from the 'Times,' be correct—that the "Act is to prevent any man *practising* Medicine who is not registered." We wish it would. And, again, he assumed that a man who styled himself Doctor might thereby be considered to imply that he was a Fellow of a College of Physicians. Not so; for the title Doctor is a University title, and the offence, if any, would be in assuming a University, and not a Collegiate status. This, however, is a disputed point, and the Licentiates of the Royal College of Physicians of Edinburgh may not inappropriately add the dictum of Chief-Baron Pollock to the other dicta on record in favour of the courtesy-right of Licentiates of a College of Physicians styling themselves Doctors.

THE POWERS OF THE MEDICAL COUNCIL.

Organ's case has been under the consideration of the Court of Queen's Bench. Mr Organ's name was struck off the 'Register' by the Medical Council, in accordance with the powers given them in the 29th section of the Medical Act. An appeal has been made against the decision of the Registrar, and Lord Chief Justice Cockburn has granted a Rule *Nisi*. The Council will, consequently, be compelled to justify the course they took. Alas! for the Medical Act! Alas! for the British Legislature!

A MARKET FOR SECOND-HAND DIPLOMAS.

If we thought the Medical Council had the courage to take a hint, we would supply them with a bit of valuable information. As it is possible, however, that it may serve some useful purpose, whether the Council interfere or not, we shall append it as it reached us, in the form of a very curious Advertisement. Here it is:—

[COPY.]

"*To Representatives of Deceased Surgeons, Surgeons and others.*—The Advertiser will purchase Diplomas from any recognised University, College or Hall, also Hospital Certificates. Dates of either not objected to, long or short. Apply in the first instance to Medicus, with price and particulars, with real name and address, West End News Rooms, 76 Strand, London."

Here is a new trade in diplomas, that threatens to outdo the business carried on in Lincoln's Inn Fields. What can the "Advertiser" want with all these diplomas and certificates? The trade in "Old Clo'" is a thriving one, because it has a useful purpose; but surely we are not to see a new grade of Medical Practitioners created by the purchase of second-hand diplomas! We are in daily expectation of seeing a hooked-nose gentleman at our door, inquiring, "Any old diplomas for sale?" We hope that the Colleges will instruct their Secretaries to look sharp after signs of erasures in the certificates presented to them, and that the Registrar will keep an equally bright eye upon the diplomas. Will anybody take the trouble to ferret out this audacious Advertiser?

DEATH OF DR WALL OF DUNMANWAY.

Our Irish readers will regret to hear of the decease of Dr Wall of Dunmanway, who was so unjustly removed by the Commissioners from his office of Dispensing Surgeon. The anxiety he suffered on that occasion is supposed to have injured his health, and to have contributed in no small degree to his untimely death. For some time past his means have been so much impoverished by his removal from office, that his Medical friends have assisted to support his family by raising subscriptions; but the present crisis has rendered necessary a more general effort. A Public Meeting has therefore been called to excite Professional sympathy in behalf of the fatherless children, and we are glad to be informed that ere the meeting closed 47*l.* were subscribed. We hope that the subscription will be sufficient to meet the wants of the family, and large enough to do honour to Irish generosity.

DR MACKESY AND THE WATERFORD CORONER.

We congratulate Dr Mackesy on the manly stand he has made in behalf of his Medical brethren in Waterford, who, it seems, have been rather harshly treated by the Coroner at various Inquests which he has recently held. The immediate motive of Dr Mackesy's justification of his brethren was an Inquest that was held on a poor woman who, whilst labouring under scarlatina, was removed, without due judgment and humanity, as it was alleged, to the hospital. The Coroner in this case, as in previous ones, animadverted with unmerited severity on the Medical Attendant; and Dr Mackesy, in his place at the Union Board, most generously and ably reproved the harsh language of the Coroner, and explained the difficulties which often surround Medical Practitioners in their treatment of poor patients. Dr Mackesy deserves well of his brethren for such noble behaviour.

THE SPIRIT OF THE PERIODICALS.

(Continued from page 359.)

We extract from the 'Medical Times and Gazette the following account of a *Visit to Graefrath*, by Dr Edwin Lee :

"Graefrath is a village of Rhenish Prussia, near Dusseldorf, which has acquired considerable celebrity from being the residence of the distinguished oculist, the Hofrath, Dr De Leuw, to whom many patients resort from foreign countries, the number of English greatly preponderating over others,—several of them remaining under treatment for a considerable time in the summer months, at which season the place is overflowing, though the accommodation is but indifferent, consisting of two or three inns of a primitive character, with plain *table d'hôte* dinner at one o'clock, and inferior lodgings. There is no resource for the recreation of patients or of friends who may accompany them ; but the environs are pleasing, and the air is of a bracing quality. The Hofrath is a spare, delicate-looking man, of about 65, of quiet, unassuming manners, intellectual countenance, and penetrating eye, not requiring the use of glasses. He does not see any patients either at his own residence or at their lodgings, the only one he has sometimes gone to visit being the King of Hanover. He has a consulting-room at the principal inn, where he remains from eight o'clock till two or three, and sometimes later, during the greater part of which time the entrance-passage —there being no waiting-room—is thronged with patients of all classes, though two days in a week are more especially allotted to the poorer class. Many patients have thus to wait for hours ; it is but seldom that a fresh comer can have an interview before a day or two. Notwithstanding this concourse, the Doctor not unfrequently gossips with patients for some time about matters in which they may be interested, which, it is said, he finds necessary, as a relaxation from the continuous employment of seeing and determining upon eye cases. As may be expected, not a few of these cases are irremediable, the patients having been induced to repair to Graefrath as a *dernier ressort*. On announcing my name and sending in a letter from a patient at a distance, I was, after a short time, cordially received, and allowed to be present during the inspection of patients, several of whose cases were of considerable interest. The Hofrath's diagnosis in obscure or difficult cases is clear and decided. His treatment—eschewing in great measure depletive means, leeches, purgatives, blistering, &c.—mainly consists of the application of unguents or lotions, of a more or less stimulating or sedative character, to the forehead and the eyes,—nitrate of silver and iodine preparations being not unfrequently employed. Mercury and other internal remedies, with a view to produce an alterative effect upon the organs, are not often administered, though internal medicines are sometimes prescribed to remedy co-existing derangement of the health. The fee for the poorer patients is very low,—about a shilling ; that for strangers, except for a single consultation, is about a Prussian dollar a visit, or they give what they please at the termination of the treatment.

"The Hofrath originally acquired reputation as an oculist by publishing, when an Army Surgeon, a work upon contagious ophthalmia, which was at that time highly thought of. He has practised in his native village for upwards of thirty years, having repeatedly refused invitations to reside in capital cities. He informed me that he had prepared for publication a work on entropion and trichiasis, for which he has operated successfully many thousand times. His method, however, as far as I could understand, does not materially differ from that usually pursued, of removing the irritated eyelashes, and excising a smaller or larger portion of the skin of the inverted lid and uniting with fine sutures. He strongly disapproves of the operation of excising the margin of the lid, as practised by a distinguished oculist of Berlin. In advanced cases of cataract he operates with the needle, puncturing the cornea (keratonyxis), as was the practice of the late Mon. Walther, of Munich,—only one eye being operated upon when both are affected, if the result be successful. He entertains, however, the firm conviction that cataract may frequently be dispersed in the early stage by external remedial means, and internal when necessary. One English patient, who was considered to be thus cured at Graefrath, had for years been almost blind, deriving no advantage from the oculists whom he had consulted. He now sees well ; but, whatever he may have had, I much doubt from his account the existence of cataract ; neither could I see any sign of this disease in a lady said to be labouring under its incipient form, whose sight, having been a good deal used in reading, &c., had failed, but was much improved under the treatment. Another English lady, however, in whom the cataract was apparent in both eyes, stated that she could see much better since she came to Graefrath. The Hofrath mentioned to me a distinguished oculist in Vienna, who formerly disbelieved the possibility of cataract being absorbed, but who had lately, in an appendix to his work, admitted its practicability. He does not allow to be known the means which he employs for this purpose, the prescriptions being only made up by the local *pharmacien*, and patients taking with them a sufficient supply of the remedies to go on with in their absence. Among the other English patients was a lady with incipient conical cornea, which had improved under the treatment. An American banker (a young man), who, from excessive attention to business, had become amaurotic, and was nearly blind, had not derived any advantage from his visit to Graefrath. As constitutional measures are not generally employed against the local disease, so also strict attention to regimen does not seem to be enforced by the Hofrath. One patient, of florid aspect, and having all the appearance of a *bon vivant*, whose eye was considerably inflamed, and who had been treated in England without success, had resided for some time in the neighbourhood, coming occasionally to visit the Hofrath, after having had a stimulating ointment (argenti nitras) put in the eye, immediately went up from the consultation to the *table d'hôte* and drank his half-bottle of wine.

"All the patients whom I saw appeared to have the greatest confidence in the Hofrath ; some, doubtless, not without good reason, having derived benefit after the failure of means employed at home ; the obscure and more difficult cases are of course the exception to the generality ; and one cause of the improvement which so many experience is doubtless greatly owing to the pure air and plain living of the place, and also to the season of the year being the most favourable (very few remain after October) for recovery, and less liable to produce aggravation or relapses. It is well known that in most Eye Institutions the bulk of the cases are less numerous and severe, and are more tractable in the summer months than at any other time of the year."

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.

Nov. 3rd.—Removal of Necrosis from Head of Femur.—Mr Fergusson. Removal of Scirrhous Breast.—Mr Wood.

Necrosis of Head of Femur.

Mr Fergusson said this case was an instance of what is called spontaneous cure—Nature's cure. The surgeon says he has performed a cure after the disease has been treated under his care perhaps five years ; Nature's cure should have been prevented by surgical interference. Much time is lost by his process, and an incomplete result obtained. This young boy, about nineteen years of age, has been under my notice a long time : I thought he might get well. Under chloroform, Mr Fergusson made an examination of the mobility of the joint. He said: There was, as you saw, great latitude of motion of hip-joint. This, nevertheless, would be considered a case of hip-joint disease of right leg. You saw I made an incision into a sinus at the back of, or posterior aspect of femur, and behind the trochanter major, and could pass my finger down very deeply. I then felt the head and neck of the bone, and after exploring with probe, felt some rough and dead bone. Some necrosed pieces of bone I brought away with nippers. I then, with bistoury, slit a sinus on the front aspect of femur, internal to the trochanter major : it seemed a very superficial sinus, as you saw, on first introducing my finger along it. You also saw the great depth to which I thrust in my finger. After a little perseverance, I brought away two very small pieces of bone. These (showing them) two small pieces had, no doubt, been the cause of all the disturbance, and of this great irritation. You see one spicula of bone has a smooth surface, indented at one extremity with a notch, where it was detached. They had, no doubt, travelled a great distance, having formed, as I believe, a necrosed portion of the os innominatum. This may be considered a true specimen of hip disease. They, as I believe, have formed a portion of the acetabulum. Mr Fergusson (holding up one of the pieces, which had a curvilinear outline and form) said : I suspect this piece of bone to have come from the margin of the cotyloid cavity. This is merely my own opinion. I have no other indication than its curved form and shape, and that it has travelled a great distance. Having removed these portions of bone, I have stuffed up the sinuses with lint, as you saw, to induce cicatrization from the bottom of the wound, and to facilitate the escape of other portions of bone, if there be such to come away. Spontaneous surgery may be carried too far, and much time be lost in hoping for spontaneous, or Nature's cure. I might in this case have resorted to excision of the head of femur, but did not think the case required that treatment. I have confidence that this simple and less formidable process may effect a cure. Perhaps more bone may yet have to be brought away.

Removal of Breast.—Mr Wood.

This patient, a woman of middle age, had a tumour which dated the origin of growth only nine months ago, but most probably had existed unnoticed for a longer period. This tumour was of singular character, free from pain, and of very rapid growth. The nipple was somewhat retracted. The breast was natural in appearance, the tumour mobile, but nodulated on the surface. The glands in the axilla were enlarged, and thickening had begun to be traced in that region. Exudation occurred from nipple of a sero-purulent and occasionally bloody fluid. The patient called this exudation milk, but Mr Wood said it was evidently cancerous juice. That the tumour was scirrhous he had no doubt, and ought, if removed at all, to be removed early. It of late increased rapidly in size. Upon explaining those circumstances, the patient willingly submitted to an operation. Mr Wood proceeded to remove the whole mammary gland and tumour ; he dissected it away close to the skin. There was little vascularity on the surface of the tumour, but the vessels were numerous when it was cut into. Mr Wood said this tumour was the opposite of the one Mr Fergusson had just before removed. This, he considered, was a pure specimen of cancer; Mr Fergusson's was simply an enlarged indurated cyst. He had to contend with large vessels in the removal of the tumour. Mr Wood said : You saw a vessel bleeding profusely on the external aspect of the tumour ; this was a branch of the axillary artery, the external mammary, which we secured, also the internal mammary. Upon making a section of the excised tumour his diagnosis was fully confirmed : of its being true cancerous, and of the existence of cancer-cells, the microscope could only determine the fact.

Nov. 10th.—Tracheotomy.—Mr Fergusson.

Several minor surgical proceedings occurred in the operating-room. Although these were unimportant in themselves, incidents transpired instructive both to professional student and veteran. Two or three cases of double hare-lip occurred, in which Mr Fergusson operated in his usual successful way. He took occasion to explain the peculiarities and modes to be adopted in this operation. One child was brought to be operated on, of remarkably healthful and robust form and appearance, and colour in the cheeks. He manifested his vigour by loud cries and struggles. This child had been previously operated upon under chloroform, and all had gone well. Chloroform was administered by Dr Anstie, with great deliberation and patience. The writer, who was close to and in front of the child, noticed its colour to have suddenly gone, and breathing to have ceased. The pulse was gone, and extremities had become quite cold, and skin a marble-white colour. Life had apparently ceased, or was rapidly flowing away. Mr Fergusson instantly applied cold water to the face and chest, beat the

chest with a wet cloth, and resorted to artificial respiration. For some time all seemed unavailing, and that all hope of restoration was evidently the prevalent idea. A laboured inspiration occurred, when all at once a slight but distinct blush came suddenly in the centre of the cheek. From this time the child gradually resuscitated, to the great relief of the anxious spectators. Mobility returned—the child became sick, and vomited a considerable quantity of pultaceous aliment from the stomach. Its restoration was complete. Mr Fergusson thought it best to defer operating until a future occasion.

GUY'S HOSPITAL.

OCTOBER 6TH.—CARCINOMA OF BREAST, EXCISION OF.—MR COCK. EXCISION OF ELBOW-JOINT.—MR HILTON.

CARCINOMA OF BREAST.

The history of this case corresponded in almost every particular with the case just recorded, operated upon by Mr Wood. The patients were of the same age (cancerous period), about fifty years. Tumours of rapid growth; this of six months' duration, or only noticed from that period—free from pain. It was also similar in showing little vascularity on surface, great internally. The gland and tumour were wholly removed, and showed upon section a truly scirrhous character. These gentlemen, in commenting upon these almost identical cases, attributed the same inevitable consequences to result. Both considered the operation only a temporary alleviation from suffering, and that an inevitably fatal issue would occur. The immunity might continue for one, two, or three years.

EXCISION OF ELBOW-JOINT.

This was a carefully-conducted operation, and of very instructive character. Mr Hilton made a longitudinal incision in the course of sinuses, on the posterior and internal aspect of the joint; the patient being a young woman, about twenty years of age. She suffered great pain, especially upon movement: chloroform was consequently administered in the ward before her removal to the operating-room. After the first longitudinal incision, Mr Hilton carried a transverse section through cartilages into the joint; then dissected out the olecranon, which he removed with strong pliers. He then dissected the joint, and with Butcher's saw removed a slice off the extremity of the humerus. By careful dissection he then exposed the head of the radius and ulna, and removed with the same saw a slice from both. Water-dressings and zinc to the bent elbow-splint were applied.

UNIVERSITY COLLEGE HOSPITAL.

EXCISION OF LARGE TUMOUR OF BREAST.—MR ERICHSEN. CURE OF HERNIA (NEW MODE).—MR THOMPSON.

AMPUTATION OF BREAST.

This patient, a strong, healthful-looking woman about forty years of age, had a remarkably large tumour of breast. She said it was of two years' growth, but was of probably longer duration. It was what is called chronic mammary tumour, free from pain or other untoward circumstances, except its weight and size, causing great inconvenience. It was nearly eight inches in diameter; when amputated, it would fill a hat. It had that peculiar conical aspect of the nipple observable in chronic mammary tumour. The tumour, growing rapidly, pressed the mammary gland under the nipple, and thus gave a conical shape to the breast, the nipple and mammary gland being the apex of a cone, and the adenoid tumour its base. It had received various names, from the time of Abernethy and Sir Astley Cooper down to the present day. These circumstances we gave a history of in describing *Adenocele* in our Reports a few weeks back. It is at present usually called *Adenocele*—a benign, if we may so speak, or non-malignant tumour. Mr Erichsen stated that he had operated upon two cases lately, in private practice, successfully. Mr Marshall, then assisting, had rendered him assistance at one of those operations. He had, as in this instance, given a correct diagnosis and history, deciding the non-malignant nature of the tumour. One of these cases, of only fifteen months' growth, was of considerably larger size than the one now amputated; the other was still of larger growth, and weighed 12lb. Mr Erichsen removed the mammary gland with the adenocele, otherwise the integument would have been too abundant to produce a good cicatrix. He made a section of the tumour, and observed that the glassy, homogeneous surface which it presented was significant of its being *non-malignant*. There were no interseeting striæ running across it, as in carcinoma, or bands to connect cells. It was what is called fibro-plastic structure. He reverted to a similar case he operated upon six weeks ago, given in our Reports at the time, which has gone away well. Mr Erichsen said—"This will heal and be discharged in a fortnight, if not attacked with erysipelas, which in so healthful a subject is unlikely to occur. The edges of the wound will quickly cicatrise." Mr Erichsen observed that when these tumours occur at the cancerous period (middle age of women), which they frequently do, they are the source of great anxiety. The two cases were greatly alike in all respects—age, personal appearance, formation, and healthful constitution.

CURE OF HERNIA.

Mr Thompson essayed and initiated an operation of his own on this occasion, his object being to obtain more decided adhesive action and inflammation that should induce a more firm cicatrix in the parts operated upon than other proceedings had hitherto effected, the want of which, he said, was the source of failure. He felt so confident of the correctness of the principle which guided the practice he was inaugurating, that whatever might be his success on the present occasion, which was not a very favourable one, he should persevere in the plan he was about to adopt. Mr Thompson remarked that he had witnessed many objections and consequent failures from all other modes. He had performed Wütrzer's operation upon the patient he was about to operate upon to-day some time since. In this case the scrotum and one were large and loose, and the weight of the abundant tissues had overcome the new cicatrices. This indicated a want of solidity and firmness of cicatrix, which he wished to obviate by obtaining a more extended surface of union. Invagination by a tube, as in Wütrzer's operation, gave adhesive inflammation at the peritoneum and conjoined tendon only, and not in the sac, which the tube effectually prevented. In consequence, the tissues, by their weight and looseness, dragged and broke down the cicatrix at the point of union, and the hernia occurred again. This would more especially take place when, upon convalescence, the horizontal is relinquished for the erect position. Instead of using the tenotomy-knife and subcutaneous division of superficial fascia, Mr Thompson invented and used a pair of spring nippers like an inverted pair of compasses. Between the grip of these he elevated and cut away a section of integument. This was done at the point which forms the commencement of the invagination. Thus obtaining two raw edges, they are then invaginated up to the internal ring, and with the index-finger the needle, which is best armed with silk ligature, is guided and pushed through the peritoneum and conjoined tendon and transversalis fascia. The end of one ligature is then freed from the needle, and the other is carried over the ring, brought out and tied tightly on the surface. The same proceeding is then had recourse to upon the external ring; the needle being passed through the tube, somewhat similar to Wütrzer's, through the invaginated tissues, and the ligatures, made to pass through and include the external ring, are tied over a circular wood-roll on the surface; the object being to bring the raw edges of the invaginated sheath into union with the parts included in the ligature, and so induce a more dense union by a larger inflamed surface upon which to set up the adhesive action. The patient was willing and anxious to obtain any mode of relief that could be suggested.

NOV. 14TH.—AMPUTATION OF SCIRRHOUS BREAST.—MR MARSHALL.

A woman, about forty-five years of age, had enlarged gland of the left breast growing for some time. The skin and nipple were retracted, and the gland showed adhesions to the integuments—the sure sign of malignant growth. Mr Marshall made a large section, removing a considerable portion of integument and the whole of the gland. He said, he removed more integument than usual, to include a hardened portion which existed at the extreme margin of the section. Upon the removal and examination of the gland, Mr Marshall described the disease as being of the character called *reticular schirrhus*,—reticular or web-like processes running in all directions through the diseased gland. These contained the cancerous fluid, which did not lie in the milk cysts, but by the side of them—the cysts themselves containing indurated or inspissated milk. He noticed the numerous vessels required in this case to be ligatured. These malignant diseases made large demands upon the circulation during their growth. He contrasted this case with the case of *adenocele* removed by Mr Erichsen last week, of which we have given a report, in which only one important vessel required to be ligatured.

A CASE OF SUPPOSED INTERNAL HÆMORRHOIDS was brought into the operating theatre under chloroform. Mr Marshall, who was called upon suddenly to officiate for Mr Erichsen, said he knew nothing of the character of the case. Upon examination, he found that it was a case of *fistula in ano*, which had been operated upon, and the incision had not been healed, but had formed fresh sinuses, running in several directions. Also prolapsus of the mucous membrane had taken place. Mr Marshall removed the large portion of mucous membrane prolapsed, and freely laid open the sinuses at the verge of the anus. He filled the wounds with dry lint, to stimulate them and induce adhesive inflammation, that they might heal from the bottom. He said, until the sinuses were healed, it was of little use removing prolapsed mucous membrane, since such removal only increases a tendency to return.

ST GEORGE'S HOSPITAL.

NOV. 8TH.—REMOVAL OF TUMOUR ON PAROTID GLAND.—MR HEWETT.

This tumour had existed for twenty-three years, consequently was of very slow growth. The patient was a young woman, about thirty years of age. Mr Hewett had been consulted about six months previously, the patient having practised, at her own suggestion, moving the tumour about, hoping by that means to reduce its size. Instead, the tumour rapidly enlarged from this treatment, and Mr Hewett recommended its removal. She was a lady's maid, and accompanied her mistress into Scotland. On her return, she agreed to its removal. Mr Hewett diagnosed, from its clean outline and long existence, that the tumour was of *fibro-plastic* structure, and, from its deep seat and slow growth, *non-malignant*. He made a deep incision over the parotid gland in the neck, through the integuments and subcutaneous tissues, and reaching the gland, found a portion of it lapping over the tumour. He carefully dissected away the gland, when the tumour beneath was found quite free, of the shape of a potato, and easily turned out. He fortunately found it quite loose and moveable, and so much detached that it turned out like a potato from a bag. In the course of its removal, Mr Hewett had to pull on one side with a tenaculum the cervico-brachial branch of the brachial nerve. In consequence, he said, there would no doubt occur more or less of paralysis of the lower part of the mouth from this unavoidable stretching of the nerve while suspended over the tenaculum. The function of the nerve would become interrupted, and paralysis is the consequence. He said this might probably continue for four, eight, or twelve months, but would in the end entirely subside. With respect to the tumour, he said he had every reason to believe it was of benign character. It had no roots, attachments, or branches extending or running into the neighbouring tissues. These circumstances give every assurance of freedom from any return. Upon cutting into it, it proved to be of *fibro-plastic* structure, and in one spot he showed that it was *cartilaginous*, being of that character of tumour called *enchondromatous*, bands of cartilage intersecting its growth. With respect to its healing, that will be by second intention. The patient being a healthful, good subject, if inflammation does not set in to induce *pyæmia*, of which, although there is a possibility, yet very little probability—or erysipelas, of which the wards are at present free—the wound will speedily heal. He said there would be suppuration, and the wound would heal in the course of a month, or earlier. The last tumour of this kind in the hospital Mr Pollock operated upon a few weeks since. In that case the wound healed in a week, and in ten days the patient left the hospital. Mr Holmes will examine the tumour with the microscope, the structure of which will be reported.

CLINICAL REPORTS OF CASES

UNDER THE CARE OF MR BAKER BROWN, AT THE LONDON SURGICAL HOME.

(Reported by Arthur B. Brown, Clinical Clerk.)

Fissure of the Rectum—Supposed Disease of the Uterus.

M. A., æt. thirty-two, married, admitted into the London Surgical Home August 6th, 1860.

History.—About two years ago was very ill, the abdomen becoming enlarged; the catamenia irregular, profuse, and lasting for a long time; and frequent flooding from the uterus.

She consulted two medical men at different times, who treated her for the flooding and flatulence, but never examined her either per vaginam or per rectum.

Her bowels have been much constipated, and she has suffered much pain on passing her motions. On her admission, she complained of a sensation of a swelling in the abdomen, which moved from side to side; great pain in the limbs, and "a tired feeling."

On Examination, Mr Brown found the uterus perfectly healthy. There was a fold of external piles round the rectum, and several internal piles; also a fissure of the rectum, with a polypoid body dropping into it.

Treatment.—August 9th.—The patient being under chloroform, Mr Brown cut off the exteroal piles, tied the internal, cut off the polypoid body, and divided the fissure. The rectum was then plugged with oiled lint.

August 11th.—Lint removed.

August 12th.—Had ℥ss. of castor-oil, which opened her bowels without any pain.

She soon after this left the Home quite cured, and Mr Brown has since heard of her as being quite well.

Fissure of the Rectum.

A. W., æt. thirty-eight, married, admitted into the London Surgical Home August 6th, 1860.

History.—About nine months ago she was ill with intermittent fever, which left her very weak. When she got better, she felt an irritating pain in her rectum, with difficulty and pain in passing her motions: she had also great pain in her back and loins. Two months ago she attended as outpatient at one of the Metropolitan Hospitals, and was there treated for hæmorrhoids, but without much relief.

On Examination, Mr Brown discovered a very bad fissure, with a polypoid body dropping into it; also two external piles.

Treatment.—She was put for a few days on tonic treatment, and on August 9th Mr Brown cut off the external piles and the polypoid body, and divided the fissure, the patient not being under chloroform. The rectum was then plugged with oiled lint.

11th.—Oiled lint removed.

12th.—Had a dose of castor-oil, which opened her bowels freely and without any pain, which she had not been free from for eighteen months.

25th.—Left quite cured.

Fissure of the Rectum—Supposed Prolapsus Uteri—Hypertrophy of Clitoris.

R. O., æt. forty-one, unmarried, admitted into the London Surgical Home October 17th, 1860.

History.—Twenty years ago, had a fall and injured her womb; an abscess formed, and discharged for some time. She has suffered from great pain in passing her motions and urine. Eighteen months ago, could not pass her water for six months, and used to have the catheter introduced. She has worn pessaries for five or six years to support the uterus.

On Examination, the uterus was found perfectly healthy; but there was a fissure of the rectum, and the clitoris was hypertrophied and felt like a piece of cartilage.

Treatment.—November 2nd, Mr Brown divided the fissure, and also divided the clitoris midway between the gland and crura. This was so hard, that it was with difficulty divided; but when cut, bled freely.

The rectum was then plugged with oiled lint. 4th.—Lint removed. 5th.—Bowels opened by castor-oil, more comfortably than they have been for years.

Remarks.—Mr Brown observed in his clinical observations on this case, that it was one of great interest, as it was evident her sufferings (which she very much magnified) arose from two causes: first the fissure of the rectum, which not only gave pain on defecation, but also produced difficulty of micturition, a very common result of fissure or fistula of the rectum; secondly, from irritation of the clitoris, which was kept up by self-abuse until it had almost lost its normal character. Mr Brown observed that he had on several occasions succeeded in curing the patient of this baneful habit by simple division of the clitoris.

Fissure of the Rectum—Supposed Disease of the Uterus.

M. F., æt. thirty, married, admitted into the London Surgical Home November 1st, 1860.

History.—Eight years and a half ago, was confined of her first child. Since then, she has had constant pain in passing her motions, and lately blood has also passed at the same time. She has for some time had great pain and bearing-down in her womb, and has been treated by many medical men for disease of that organ.

On Examination, Mr Brown found the uterus perfectly healthy; but on examining the rectum, discovered a fissure and two small polypi.

Treatment.—November 3rd, Mr Brown divided the fissure, removed the polypoid bodies, and plugged the rectum with oiled lint.

5th.—Lint removed. Had ℥ss. of castor-oil, which opened her bowels with more ease than had been done for nine years.

12th.—She now has daily evacuations without the slightest pain, and expresses herself as being free from all her old inconvenience.

MEDICAL SOCIETIES.

EPIDEMIOLOGICAL SOCIETY.

MONDAY, NOVEMBER 5, 1860.

DR BABINGTON, PRESIDENT, IN THE CHAIR.

A paper, by Professor SIMPSON, of Edinburgh, was read by Dr MCWILLIAM, entitled

NOTICES OF THE APPEARANCE OF SYPHILIS IN SCOTLAND, IN THE LAST YEARS OF THE FIFTEENTH CENTURY.

Dr SIMPSON's paper commenced by stating that Medical men are for the most part agreed upon two points in relation to the history of syphilis—viz., that it is a species of disease which was unknown to the Greek, Roman, and Arabian Physicians; and that it first began to prevail in Europe in the latter years of the fifteenth century. The non-existence of syphilis in ancient times, and the circumstance of its original appearance in Europe, about the date alluded to, are opinions strongly borne out by two sets of facts. For, first, no definite account of this marked and extraordinary species of disease is to be found in the writings of any one of the ancient Greek or Roman physicians, historians, or poets; and, secondly, of the numerous authors whose works exist in the learned collections of Liusinus, Astruc, and Girtanner, and who saw and deseribed the malady in the latter years of the fifteenth, or commencement of the sixteenth century, almost all comment upon it as (to use their own general expressions) "*Morbus Novus,*" "*Morbus Ignotus,*" &c., &c. "It would not, however," said Dr Simpson, "affect our present object, were we to consider the disease as it appeared about the period in question, not to have been a new malady previously totally unknowo, but merely, as some have thought, an aggravated form of a disease, formerly existing in so mild a form as not to have attracted general observation." Dr Simpson considered it unnecessary to investigate the question of the probable source of the disease, and the exact date at which syphilis first burst forth in Europe. In relation to the object he had in view, it mattered not whether it sprung up spontaneously and endemically in Spain, Italy, or France, at the era in question, or was imported from Africa, as Grüner and others allege, or from Hispaniola, as Astruc, Wetherhead, and a host of authorities have stoutly, and not unsuccessfully, maintained. Nor was it necessary to discuss whether it first showed itself in 1493, as Sanchez and Hensler consider that they have proved; or in 1492, as Fulgosi asserts; or as early even as the month of October, 1483, as Peter Pinctor, in 1500, proved astrologically to his own complete satisfaction that it ought at least to have done, inasmuch as that was, as he has sagaciously shown, the precise and exact date of the conjunction of Venus with Jupiter, Mars, and Mercury; and the conjunction of these or other stars in the heavens above, was, as he and many of the Astrological Physicians of his time believed, the origin of this new scourge on the earth below. Dr Simpson started from the general proposition, that the disease was in 1494 and 1495 first distinctly recognised in Italy, during the invasion of that country by the victorious army of Charles VIII. of France. The malady is generally allowed to have earliest broken out, in a marked degree, at Naples, about the time that Charles took possession of that city in the spring of 1495, or nearly two years after Columbus's return from his first voyage to Hispaniola. Charles set out again for France in May, 1495, and the malady seems to have been both diffused by his infected troops along the line of their northward march, and afterwards carried to their respective houses by his own French soldiers, as well as by his various Swiss, German, and Flemish auxiliaries. The new malady was not long in reaching Scotland, as attested by edicts issued in 1497 by the Town Council of Aberdeen, with reference to the appearance of the disease there, and by the Privy Council in Scotland in relation to its prevalence in Edinburgh. By the Aberdeen edict it was "stated and ordainit, that all licht wemen be charg'd and ordainit to decist fra thar viees and syne of venerie,"—and a few years later, "that diligent inquisition be taken of all infect personis with this strange seikness of Nappelis." The Edinburgh edict was six months later in date than the first of those issued by the Aberdeen authorities. It was, as already stated, drawn up by the King's Privy Council, and proceeds thus: "It is our Soveraine Lordis will, and the command of the Lordis of the Counsall, sent to the Prouest and Baillies within this Burgh, that this proclamation follow and be put into execution for the eschewing of the greit apperand danger of the infection of his Lieges fra a contagious sikness callit the Grandgore, &c. That is to say, We charge straitlie and command that all maner of personis, being within the Fredome of this Burgh, quhilk are infectit or has been infectit, and incurit of this said contagious Plage callit the Grandgore, devoyd, red, and pass furth of this Town, and Compair upon the sundia of Leith, at ten houris before none, and thair sall have and synd Botis reddie in the Haven ordainit, to tham be the Officary of this Burgh reddilie furneist with victuales, to have thaim to the Inch, and thare to remain quhile God provide for their Health." The edict further ordains that those who take upon them the cure of the disease are also to pass with the "infectit" to the inch; and disobedience on the part of the Doctor or his patient, rendered both alike amenable to the penalty of being "brynt on the cheek with the marking irne, that they may be kennit in time to come." At the time of the first appearance of syphilis in the northern realm, the throne of Scotland was occupied by James IV., a prince who was a great patron of the arts and sciences of his time. At different times we find him experimenting in Chemistry, in Physiology, and in Medicine. His daily expense-books contain many entries of purchases for instruments and materials to make the unmakeable "Quinta Essentia," or philosopher's stone; and he had laboratories for these investigations both at Edinburgh and Stirling. King James practised the art of Leech-craft, as well as experimented in Alchemy and Physiology. "He was," says Lindsay of Pitscottie, "weill learned in the airt of Medicine; and was ane singular guid chireirgiane; and their was none of that profession, if they had any dangerous cure in hand, but would have craved his adwyse." The High-Treasurer's account shows that the King had a right royal way in one important respect with his patients, that by it he might have secured a large consulting and private practice, even in these modern days of high rivalry and competition; for he paid his patients, instead of being paid by them. Thus, in his daily expense-book, under the date of April 14, 1491, is the following entry:—"Item—To Dominico, to gif ye King leve to leif him blud," eighteen shillings Scotch: and a short time afterwards, "Item—To Kynnard ye barbour, for twa teith drawn furth of his hed be ye King, xviii. shillings." He seems also to have tried his hand at Ocular Surgery; but the following entry rather ominously hints that he was not a successful operator for cataract:—"Item—Giffin to ye blind wif yat had her ein schorne, xviii. shillings." A prince imbued with

such Medical and Surgical propensities would naturally feel deeply interested in the first appearance within his realm of such a malady as syphilis; and in his Treasurer's accounts there are several entries indicated that the King had bestowed monies upon various persons affected with this disease. Thus there are several entries between September, 1497, and April, 1498, for sums awarded to persons of both sexes afflicted with "Grantgore." There are various sarcastic allusions to the disease by the Scottish poets of these early days, amply testifying to the fact of its rapid diffusion, both among the *attachés* of the Court (who were then the most common objects of poetical satire), and among the community at large. William Dunbar, the flower of the old Scottish poets, was at the first introduction of syphilis, in 1497, in the prime of manhood; and in two or three years afterwards, viz., in 1500, was attached to the King and Court of James IV. by an annual State pension. In a number of versea addressed to his patroness the Queen—verses which strongly appear to us at the present day, with our existing standards of taste, as most unseemly and indecent he commemorates the communication of the new disease under the name of the "pockis," or the "spanyie pockis," to the Queen's men, during the jollities of Eastern's e'en, and the reign of the "Abbott of Unreason," and he closes his stanzas with an earnest advice to all to

"Bewar with that perillous play,
That men callis libbing of the Pockis."

The after effects and consequences of the disease he describes thus,—

"Sum, that war ryatous as Rammis
Ar now maad tame like ony Lammia;
And sittin down lyke Scange Crockis;
And has forsaken all sic gamios
As men cā libbing of the Pockis."

Grunbecht and Brandt, who wrote on syphilis in 1496, when speaking of the diffusion of the disease at that early date over Europe, both allude, in very general terms, to its having invaded France, Germany, &c., and reached as far as "Brittain." But the earliest specific notice of syphilis in England which Dr. Simpson remembers to have met with, is in 1502; and in this notice the malady is spoken of under the name of "French pox." This notice is contained in the interesting Privy Purse Expense-Book of Elizabeth of York, the Queen of King Henry VII., edited by Sir Harris Nicholas. This charitable lady seems, from the records in question, to have had several *protégées* under her immediate care and keeping. Among these *protégées* is entered John Pertriche, "one of the sonnes of mad Beale." There are various articles of expenditure successively noted in the Queen's private expense-book as lavished upon this John Pertriche during the currency of 1502, as 'monies' for his 'dyetts,' for 'buying shirts,' 'shoyn,' 'hosen,' &c. There are twenty pence expended for his 'Learnying,' and the last two items in the account record attempts of two different and rather opposite kinds, to amend the mental and moral deficiencies of this hopeful youth. These two ultimate items are:—"For a Prymer and Saulter Book to (John) xx pence," and "Payed to a Surgeon which healed him of French pox xx shillings."

In the second division of his paper, Dr Simpson observes, that the preceding noticea, however brief and imperfect, relative to the first introduction and dissemination of syphilis in this country, were not simply matters calculated to gratify mere antiquarian curiosity. They appeared to him to be capable of a much higher application, For they offered so many elements tending to illustrate the general history of the first appearance of syphilis in Europe, and justify us in drawing from the data they afford, several not uninteresting nor unimportant corollaries in regard to the first origin and mode of propagation of the disease, and the distinction of it from other affections with which it has been confounded. I. These notices tend to corroborate the pathological opinion, that syphilis was a species of disease new to Europe when it first excited the attention of Physicians, and historians, in the last years of the fifteenth century. If syphilis was new in Britain in the end of the fifteenth century, this shows, II. That it is a species of disease distinct and different alike, 1st, from gonorrhœa, and, 2nd, from Greek leprosy (with both of which maladies it has occasionally been confounded), for both of these maladies existed, and were abundantly recognised in this country, long before the era of the introduction of syphilis. III. As regards the mode or modes in which the disease was supposed to be so speedily propagated at its first appearance in Europe, the Aberdeen and Edinburgh records are both interesting, though they offer very opposite testimony on this point. For some time after syphilis broke out, it was believed both by the Medical and non-Medical public, that the disease was communicable and constantly communicated from the infected to the healthy, by the employment of the clothes, vessels, baths, &c., used by these already suffering from it, and by the slightest corporeal contact, or even by breathing the same air with them. One of the gravest articles of guilt brought against Cardinal Wolsey, when he was arraigned by the House of Lords in 1529, consisted in the allegation that, to quote the *ipsissima verba* of the indictment as laid before Henry VIII., "Whereas your Grace is our Sovereign Lord and Head, in whom standeth all the surety and wealth of this Realm, the same Lord Cardinal, knowing himself to have the foul and contagious disease of the great pox broken out upon him in divers places of his body, came daily to your Grace, owning in your ear, and blowing upon your most noble Grace with his perilous and infective breath, to the marvellous danger of your Highness, if God of His infinite goodness had not better provided for your Highness," &c., &c For some years after the first outbreak of the disease, sexual intercourse with the infected does not seem to have been suspected by any one as the source and means by which the syphilitic contagion was propagated; nor was the primary affection of the several organs generally noticed by the authors of these times as a constant or marked symptom. They were acquainted with, and described only, the secondary symptoms of the malady—the hideous eruptions on the skin, the ulcers of the throat, the exostoses and nocturnal pains in the bones—while they mostly all pass over the genital organs as if they remained unaffected. So much was this the case, that we find Montagnana, in 1498, recommending, not as a means of infection, but as a means of cure, moderate coition (*coitus temperatus*). Montagnana speaks of having recommended the treatment in question (*coitus temperatus*) to a sick bishop under his care; and perhaps we may venture to guess that such a prescription would neither be the most disagreeable medicine in the world to one who had taken upon him the vows of St Benedict, nor the one least likely to extend Montagnana's practice among the same class of patients. IV. The early notices (continued Dr Simpson) adduced of the appearance of syphilis in Scotland are curious, as proofs of the rapidity with which the disease travelled at its first outbreak over the kingdoms of Europe. The new malady was, as has already been stated, first distinctly recognised during the period that Charles VIII. of France occupied the city of Naples, or rather immediately after he left that place. That Naples was the locality in which the contagion first spread so widely and rapidly as to be considered almost the source of the new epidemic; and further, that this happened at the precise date of the visit of the French army—seems to be shown by the very designations respectively conferred at the time upon the new affection by the Neapolitans and French. For while the French, as it is well known, designated it at its first commencement "the Neapolitan disease," the Neapolitans, on the other hand, termed it "the French disease." The army of Charles in their march through Italy arrived at Rome on the 4th of December, 1494, and entered Naples on the 21st of February, 1495; and after remaining there three months, they evacuated the city on the 20th of May. On the 4th of the same month, the Spanish General, Cordova, landed in Sicily; on the 5th of July the battle of Torrenovo was fought, and the next day King Ferdinand returned to Naples, but the last remnant of the French army did not reach France till the end of the following year. The Aberdeen edict, however, was issued within less than two years after Charles commenced his march homeward. Or, to state the matter otherwise, Columbus arrived at Palos, in Andalusia, after his first voyage to the New World, on March 15, 1493, and from his second voyage in April, 1496. The edict of the Aberdeen Aldermen and Council was passed on April 23, 1497, or exactly four years and thirty-eight days from the date of Columbus's first return to Europe; while the famous edict of the Parisian authorities was issued on March 6, 1497, only forty-eight days before that of Aberdeen. The rapidity with which the disease thus spread from the south of Europe to its western confines has been often employed as an argument to show that the contagion of syphilis was propagated at its first introduction by laws different from those which now regulate its communication. In other words, it has often been alleged that the disease was thus spread from kingdom to kingdom, and from city to city, by epidemic influence, and by general contagion, and not merely by the slower medium of impure sexual connection. When we look to the then existing state of society, both on the Continent and in our own country—to the loose manners and licentious lives—we shall probably find a sufficient solution of the, at first sight, difficult problem of the rapid dissemination of the new malady. The morals of the general mass of the people are ever found to be regulated by the example set before them by the aristocracy and clergy. At the date of the introduction of syphilis into Europe, the notorious habits of the two latter ruling bodies were assuredly such as to expedite the diffusion of the new scourge that had sprung up among them, and hence at its first outbreak we find the disease forcing itself upon several of the highest members of the Continental Court and Church. The Emperor Charles V., Pope Alexander VI., kings and cardinals, princes and bishops, peers and priests, are recorded among its victims. As far as regarded the predisposing habits and influence of the clergy at least, matters were not better in Britain than on the Continent when the disease reached this country. There was openly inscribed over the door of Cardinal Wolsey's palace,—"Domus Meretricium Domini Cardinalis." The manners of the inferior dignitaries of the church offered only too close an imitation of those of its Primate. The Commissioners appointed by Henry VIII. to visit the monasteries of England have recorded a sad, and probably only a too true, picture of the moral degeneracy of the great mass of the clergy of the time. With some few honourable and cheering exceptions, they found the occupants of the monasteries "following lives of degraded vices and licentiousness, instead of religious purity and exemplary rectitude." Accounts of their proceedings were transmitted by the Visitor to the Vicar-General, and they contained sufficient material to render the monasteries "completely infamous, for their gross, absurd superstition, their shameful impositions, their abandoned, unnatural incontinency," &c. &c. Clerical morals and manners were not in a much better state on the Scottish side of the border. Queen Mary would seem to have regarded the health of the high Roman Church dignitary who baptised her son James with considerable suspicion, for she sent word to him to forbear to use the "spittle" on the occasion. "She would not have a pokia priest to spit in her child's mouth." Very shortly before the commencement of syphilis, the dissolute manners of the English clergy, especially of the regulars, created such noise and commotion, that Pope Innocent VIII. sent, in 1490, to Archbishop Merton, authorising him to admonish his abbots and friars, "that by their lewd and dissolute lives, they brought ruin upon their own souls and set a bad example to others." When such was the scandalous life led by some of the clergy, we cannot wonder (concluded Dr Simpson) that before the introduction of syphilis, Rabelais (himself at one time an ecclesiastic) should apply to gonorrhœa the very significant term of "Rheume Ecclesiastique;" or, that after the appearance of syphilis, this latter and greater malady should have spread speedily among all ranks, down from the clergy to the laity, and from the king to the church, and should have diffused itself by such stealthy and rapid steps over the countries of Europe, as to have at first been mistaken for a malady spreading itself, not by impure intercourse, but by general epidemic influences.

A discussion followed the reading of this paper, in which Dr Copland, Dr Babington, Mr Hunt, and Dr McWilliam took part.

Robbery of Surgical Instruments.—At the Marlborough-street Police Court, John and Susan Farmer were charged with stealing surgical instruments, the property of Mr Bailey, surgical instrument maker, of 418 Oxford street, from whom a large number of instruments had been stolen out of a glass case in the shop. They had endeavoured to dispose of them to a surgeon, and when they were apprehended had in their possession several cases of instruments, which were identified. The prisoners were remanded.

OUR NOTE BOOK.

GLYCERIN LOTION.

Take of rose-water, 1 pint; quince-seed, 2 drachms. Macerate, strain, and add glycerin 1lb. This is an elegant application to chapped hands, and may do very well for a hair-dressing. Rose-water may be substituted by orange-flower water, or other aqueous perfumes.—'Chemist and Druggist,' and 'British American Journal.'

HYPODERMIC MEDICATION BY SULPHATE OF QUININE.

The subject of hypodermic medication is now attracting much attention. Much has been said about its great efficacy in neuralgic affections, where the effect is supposed to be a local one, though, at times, the constitutional symptoms are quite marked.

The results of experiments performed by Dr I. Langer, of Davenport, Iowa, with sulphate of quinine, and reported in the 'New York Medical Press' for June 16, 1860, prove that this drug, at least, acts after its absorption. The article is quite lengthy, but the following conclusions contain the substance of the Author's labours:

"1st. Certain agencies most powerful when hypodermically used, will become inefficacious when administered in stomach doses.

"2nd. Sulphate of quinine injected into the areolar tissue will act quicker, more powerfully, and with equal, if not more, certainty in subduing the primary symptoms of malarial infections, than when administered by the mouth.

"3rd. Sulphate of quinine injected under the corium even in large doses, one scruple at one injection, will not produce excessive cephalic symptoms.

"4th. Sulphate of quinine injected under the corium, if necessary, during a paroxysm, will be followed with less aggravated symptoms than in a stomachic dose.

"5th. Where the sulphate of quinine is indicated, the local irritation of the stomach and appendages constitutes no contra-indication.

"6th. The injection must always be made under the corium.

"7th. The solution must be rendered neutral, to avoid unnecessary pains.

"8th. For the same purpose—also for dissolving the crystals sometimes precipitated in a solution of the sulphate of quinine—the temperature of the solution must be increased to blood-heat and over.

"9th. Sulphate of quinine hypodermically applied is received into the system in a greater state of purity than when given by the stomach, where it may become contaminated or decomposed."—'Boston Med. Journal,' Aug. 2, 1860, and 'British American Journal.'

ON RETENTION OF URINE IN THE FŒTUS AS A CAUSE OF OBSTRUCTED LABOUR.

The substance of this paper constituted a communication to the Academy of Medicine some years since, but has never been before published in full. Judging from the silence of writers on Midwifery upon this subject, M. Dépaul observes, this cause of difficult labour can be little known. But although cases of retention of the urine in the fœtus carried to this extent may be rare, others are far more common, in which, owing to the secretion having continued during a less lengthened period, or having been less abundant, the tumour resulting from its accumulation has been much less considerable, or may have passed unperceived at the period of birth. At present, the Author confines his attention to the obstetrical relations of these cases, proposing on a future occasion to demonstrate the fact now generally denied—viz., that the functions of the kidneys become established at an early period of fœtal life, the urine passing, by reason of the bladder, through the canal of the urethra into the liquor amnii, of which it is indeed one of the principal sources. The following is an abstract of the particulars of the case which occurred in M. Dépaul's own practice, and related by him at great length:

A lady, twenty-eight years of age, in her third pregnancy, found at the fifth month that she had attained the size usual at the end of gestation, this exaggerated size having begun to manifest itself after three months and a half. The movements of the child, too, perceived first at about the fourth month and a half, were very feeble, and kept getting more and more so. Soon after the sixth month labour pains appeared, and in the course of twenty-six hours dilatation had become complete. Notwithstanding, however, that the pains of late had become very active, no progress seemed to be made, and no liquor amnii was discharged. The midwife, wishing to expedite matters, used various violent tractions, the consequences of which were that the cervical spine became broken, and one arm and the head were detached from the body. A practitioner who was called in detached the other arm and opened the thorax; but notwithstanding the evacuation of the lungs and heart, the trunk could not be delivered. After eight hours endeavour of this kind, the Author's aid was sought, the pains having now become feeble, but the patient's condition being in no wise alarming. He was at once struck by the enormous size of her abdomen, the fundus of the uterus extending six fingers' breadth above the umbilicus, while the organ had assumed the size of a uterus at full time when distended with a large quantity of liquor amnii. On examination, the abdomen of the infant was found to be enormously distended, and this was at first attributed to ascites, although such large effusions into the peritoneum during intra-uterine life are very unusual. An opening into the abdomen was forced by means of the finger, and about a quart of sanguinolent serosity was discharged. Notwithstanding this, it still continued immensely distended, and a fluctuating tumour was still to be felt. Perforating this with the nail, a quantity of transparent, citron-coloured fluid gushed out, which was estimated at about five pints. After this discharge the delivery was easily completed, and the patient did as well as after a natural labour. On examining the fœtal abdomen, and restoring it by means of insufflation to the large size it had prior to the punctures, it was found to measure twenty-one centimetres in the transverse, nineteen in the vertical, and fourteen in the antero-posterior diameters—and this independently of the increase which had taken place from effusion of serosity into the peritoneum. The abdominal walls themselves had also undergone a considerable thickening from serous infiltration. The distended bladder, the muscular walls of which were much hypertrophied, occupied almost all the cavity of the abdomen, the organ being in its largest circumference thirty-five centimetres. Three canals opened on its surface,—the two ureters, and the large intestine. The last terminated on the anterior side (its normal calibre having become diminished after coming in contact with the bladder to that of a small quill), its aperture being scarcely detectable. Externally there was no indication of the orifice of the anus. The immediate cause of the urinary tumour was the obliteration of a portion of the canal of the urethra.

M. Dépaul quotes in detail cases more or less resembling this one related by Portal, in his 'Pratique des Accouchements;' by Mr Fearn, in vol. ii. of the 'Lancet' for 1834-35; by M. Delbovier, in the 'Archives de Médecine Belge;' by M. Gaudon, in the 'Bulletins de la Société Anatomique' for 1846; and by M. Duparcque, in the 'Annales d'Obstetrique' for 1842; and from the whole he draws the following conclusions:—1. The urinary secretion is established at an early period of fœtal life. 2. When, from vicious conformation or other obstacle, the urine cannot at this period of life be expelled into the cavity of the amnios, it accumulates in the bladder, and this organ may then obtain dimensions which renders spontaneous delivery impossible, even when the pelvis is perfectly well formed, and the period of pregnancy is not complete. 3. So great have been the difficulties thus produced, that in several cases the head and limbs have become detached without the obstacle being overcome. 4. Whenever an examination of the parts has been made with exactitude, it has been plainly demonstrated that, together with this development of the size of the bladder, there has coexisted a hypertrophy of its walls, and especially of its muscular coat, showing that the organ does not play merely the part of a passive reservoir, but that it frequently endeavours, during pregnancy, to expel the fluid which it has received. 5. The cases on record would seem to show that while it may be well-nigh impossible to recognise the nature of such a case during pregnancy, a strong probability, if not certainty, may be arrived at respecting it during the progress of labour. 6. The rarity of simple ascites carried to this extreme degree, will at once lead to the presumption of a distension of the bladder; a retention of urine may be declared to be present when malformation of the genital organs may be made out by exploration. 7. Under any circumstance the practice to be pursued is the same. When tractions, carried as far as prudence will permit, have failed, an evacuation must be resorted to. 8. As the vices of conformation of the urinary organs in question do not necessarily compromise the viability of the infant, it is absolutely necessary to practise the operation of puncture with all due precaution. The insertion of the funis will serve as a safe guide to the most favourable spot. 9. In proceeding in this way, it may not be impossible, by means of another operation, performed after delivery, to re-establish the natural passage of the urine, and thus save the life of the child.—'Gazette Hebdomadaire,' Nos. 20, 21, 23, and 'British American Journal.'

ALUM LOZENGES FOR APHTHÆ AND PHARYNGO-LARYNGEAL ANGINA.

Instead of the alum gargles prescribed for pharyngo-laryngeal angina, the aphony or disphony of professional singers, and for aphthæ of the mouth, whatever be their origin, M. Argenti exhibits with benefit the following lozenges:

℞—Aluminis . . . . .
Tragacanthæ . . . .
Sacchari . . . . . } ā q. s.
Aq. destill. lauro-cerasi

for lozenges weighing 7 gr. and containing each about half a grain of alum.

The well-mixed mass is spread over a sheet of paper, distributed into lozenges, and dried at a mild heat. The result is a pastil in which the astringent taste of the alum is tempered by the sweetening ingredients, and will keep for months. The lozenge is allowed to melt in the mouth, and the saliva conveys the medicinal agent to the diseased parts.—'Journal of Practical Medicine and Surgery.'

LEGAL INTELLIGENCE.

COURT OF EXCHEQUER, Nov. 14TH.

(*Sittings in Banco, before the* Lord Chief Baron, Mr Baron Bramwell, Mr Baron Channell, *and* Mr Baron Wilde.)

ELLIS *v.* KELLY.

This was a case stated under the 20th and 21st of Victoria, cap. 43. An information was preferred against the defendant, a surgeon at Pinner, for having, on the 2nd of November last, pretended to be, and using the title of, Doctor of Medicine, thereby implying that he was registered under the Act 21st and 22nd of Victoria, cap. 90.

It was proved before the magistrates that the defendant had for years past affixed on the outer gate of his residence a brass plate, on which was engraved "Dr Kelly." The defendant was registered in the last 'Medical Register' as a member of the Royal College of Surgeons of England, 1856; licentiate of the Society of Apothecaries, 1856. The complainant swore that he had heard him call himself Doctor Kelly.

For the defence, a document, purporting to be a diploma of the University of Erlangen, in Bavaria, was put in, and evidence was called to prove the genuineness of it.

Gustavus Morris Strauss, Doctor of Philosophy, of Berlin, swore that he was acquainted with the diplomas of the University of Erlangen, and one of the seals attached to the diploma produced was that of the great University; that the second seal was that of the Medical Faculty; that the diploma permitted the person named therein to practise Medicine throughout Germany, and that he believed the signature of one of the professors (Rowsshuit) to be genuine.

Adolph Reinecher, Doctor of Medicine, of Berlin, swore that the diploma in question was in the form and shape of those used at Erlangen, but that the seals are not like those at present used; that formerly diplomas of Philosophy of German Universities were to be had for money, but not those for Medicine, persons residing in England being unable to obtain one without first undergoing examination.

The complainant contended that the diploma put in was not legally proved to be authentic and genuine, nor the person named therein to be the defendant; and that the same might have been proved if the defendant had left the document at the Registration office, when the Council would, through the Dean of the Faculty at Erlangen, have ascertained the fact of its being genuine or not; and that even if these facts had been duly proved, the defendant not being registered as qualified by that diploma to practise

as a M.D., he did not commit the offence charged in the information by having the title of doctor on his brass plate in front of his house; and also that the possession of such foreign diploma did not entitle the defendant to use the title of doctor of medicine in this country without being liable to the penalty imposed by the 40th section of the 21st and 22nd of Victoria, cap. 90.

The Justices, upon hearing the information, dismissed the same, with costs against the complainant, for the following reasons:—That it was proved the defendant had practised at Pinner as a medical man, assuming the title of doctor of medicine, and was not registered in the Medical Register as such; that the document purporting to be a diploma was not proved; that the possession of that document so far justified the defendant in assuming the title of doctor of medicine; that he could not be said to have assumed such title wilfully and falsely within the meaning of the 40th section of the Registration Act: but the Justices were of opinion that the Act prohibited in England the use of the title of doctor of medicine obtained by virtue of any foreign diploma, unless the same be registered according to the provisions of the Act. The questions stated for the opinion of the Court were—first, whether the Medical Registration Act, 21st and 22nd Victoria, cap. 90, prohibits the taking and using the title of doctor of medicine by any medical man in England unless the said title be duly registered according to the provisions of the Act; secondly, whether, if the Court should be of opinion that the Act prohibits the assuming of such title, the defendant under the circumstances can be held to have so done "wilfully and falsely" within the meaning of the 40th section.

Mr Codd argued for the appellant; Mr Coulson Robinson, for the respondent.

Mr Codd submitted that the opinion of the Court should be in the affirmative on both questions; that the Act prohibited the use of the title of doctor of medicine, and that there was no evidence to justify the justices in assuming his title from the parchment produced before them. Sect. 34, 21st and 22nd of Victoria, cap. 90, enacts that a duly-qualified medical practitioner shall be construed to mean "a person registered under this Act." The 40th section enacts "that any person who shall wilfully and falsely pretend to be, or take or use the name or title of, a physician, doctor of medicine, licentiate in medicine and surgery, bachelor of medicine, surgeon, general practitioner, or apothecary, or any name, title, addition, or description implying that he is registered under this Act, or that he is recognised by law as a physician, &c., shall, upon a summary conviction for any such offence, pay a sum not exceeding 20*l*." The question is, whether, upon the wording of the Act, the fact of having a foreign diploma gave the defendant a colourable right to use the title of a physician. The magistrates did not think the seals to the diploma proved, and the evidence of its authenticity failed.

The Lord Chief Baron: The seals are both proved according to the evidence stated in the case before us.

Mr Codd: The justices say the contrary.

The Lord Chief Baron: When we revise the decision here, we may say that the seals are proved, although the magistrates say they are not.

Mr Codd: I contend that a person duly qualified, but not registered, comes within the 40th section; his non-registration is a violation of it.

The Lord Chief Baron: But the defendant is registered both as a surgeon and an apothecary.

Mr Codd: But not as a M.D., which he described himself to be. He wilfully and falsely pretends to be what he is not, and comes within the Act.

The Lord Chief Baron: If a man is registered, he may call himself what he pleases. Suppose a person is a surgeon and a doctor of laws, which might happen, surely he can call himself doctor if he thinks proper to do so! The Act was passed to prevent persons not being qualified to practise surgery imposing upon the public. The defendant is qualified and registered, and you can only charge him with assuming to be a member of the College of Physicians, when he is only in reality a member of the College of Surgeons. There is no pretence for saying that he pretended to be a member of the College of Physicians. The charge virtually here is not that he assumed a name, but that he did not drop it.

Their Lordships were ultimately of opinion that the decision of the Justices should be confirmed, and granted the costs of the appeal.

In the Court of Queen's Bench at Westminster, on Nov. 15, the case of the Queen *v.* the Registrar of the General Council of Medical Education and Registration of the United Kingdom was brought before Lord Chief Justice Cockburn, and Justices Hill and Blackburn. Mr Serjeant Hayes moved for a rule calling upon the Registrar of the General Council of Medical Education and Registration to show cause why the name of the applicant, R. Organ, should not be restored to the Register, from which it had been erased by order of the Council. It appeared from the statement made by the learned serjeant, that the 46th section of the Medical Act (the 21st and 22nd of Victoria, cap. xc.) authorised the General Council to dispense with such provisions of the Act, or regulations made under it, as to them should seem fit, in favour of certain classes of practitioners, among whom were enumerated "persons practising in the United Kingdom on Foreign or Colonial diplomas or degrees." The applicant sent in an application to have the benefit of this dispensation, as being in practice on a foreign diploma. The Council did not recognise his claim on the ground which he put forward, but allowed his name to be registered under another clause of the same section, viz., as acting "as Surgeon in the public service," the applicant being Surgeon to several Poor-law Unions in Yorkshire. Subsequently they caused his name to be erased from the Register, in accordance with the power given to the Council by the 59th section, which enacted that if a registered Medical Practitioner shall be convicted of any felony or misdemeanour, "or shall, after inquiry, be judged by the General Council to have been guilty of infamous conduct in any professional respect," the General Council might, if they saw fit, direct the Registrar to erase his name from the Register. There was also another section, the 26th, which enacted that any entry which shall be proved to the satisfaction of such General or Branch Council to have been fraudulently made may be erased from the Register, by order in writing of such General or Branch Council; and the Council contended that they were justified in erasing the applicant's name under that section; also, it being alleged that he had procured his name to be registered by a statement that he had been duly appointed Surgeon to certain Unions, the fact being that, in at least one of the instances specified, he had no regular appointment. The learned serjeant now stated that the applicant had not claimed to be registered as a Surgeon "in the public service," but as "practising on a foreign diploma;" and he contended that the 30th section was prospective only, and not retrospective; and, as the "infamous conduct" of which it was alleged the applicant had been guilty took place many years ago, the Medical Council had no jurisdiction to inquire into it. Lord Chief Justice Cockburn said the question required serious consideration, and the learned serjeant might take a rule.—Rule *nisi* granted.

DR CHARLES COOTE.

It is with great sorrow that we have to announce the death of Dr Charles Coote. A career of usefulness opening with brighter prospects than usually falls to the lot of one so young has thus been suddenly brought to a close; and when we say he died respected and esteemed by all who know him, we feel that we are expressing a sentiment very generally felt.

Charles Thomas Coote was the fourth son of R. H. Coote, Esq., Barrister, of Lincoln's-inn. He was born in the year 1823. His early education was acquired at the Kensington Proprietary and King's College Schools, whence he proceeded to Queen's College, Oxford, intending at that time to enter the Church, his mind having been attracted to theological studies by the movement which began in the Church of England under the name of Tractarianism. In this study he continued for several years, and obtained with honours his degree of Master of Arts in 1847. But here his active mind took another turn, and he migrated to Pembroke College, devoting his attention to the more attractive studies of Medicine and Natural Science; and again he gave evidence of the talent which he possessed by gaining the Shepherd Medical Fellowship of his College. He now entered on the practical study of his Profession at St Bartholomew's Hospital, and, a short time afterwards, obtained the Radcliffe Travelling Fellowship. In 1853 he took his degree as Doctor of Medicine at Oxford, and in 1858 was elected a Fellow of the Royal College of Physicians.

Having now finished his Professional education in England, he married, and proceeded to visit the various Continental Medical Schools, being for some time a pupil under Rokitansky at Vienna, and Virchow at Wurtzburg. But here a sad trial overtook him—his wife died; and this shock so shattered his health that he returned home, aged by much more than the time he had spent from England.

The war in the Crimea soon followed, and Dr Coote went out as one of the Assistant-Physicians to the British Civil Hospital at Smyrna. Upon his return to England he became attached to the Great Northern Hospital, which he afterwards relinquished on being appointed to the staff of the Middlesex Hospital, which appointment is now made vacant by his death.

His untiring energy and perseverance, his constant attendance in the post-mortem theatre, soon told upon a frame already shattered by domestic affliction, and weakened by his Eastern labours. He rapidly lost flesh and strength; and being advised by his colleagues to try change of air, he proceeded to St Leonards, and afterwards to Hières, in the South of France. For a short time he seemed to derive evident benefit, and the accounts which reached home were very encouraging; but this was only of short duration. He was found dead in his bedroom on the morning of the 13th inst., having died apparently from some cardiac affection.

We gladly append the following resolution unanimously agreed to by his late colleagues, as expressing the feelings with which he has inspired them during the short time he held office at the Middlesex Hospital:—

"The Medical Committee have the painful duty to announce at the Weekly Board that they have received the distressing intelligence of the death of their esteemed colleague, Dr Charles Coote. The Committee cannot make this communication to the Weekly Board without at the same time expressing their deep sense of the loss the Hospital has sustained in the premature decease of one whose extensive acquirements, untiring energy, and great practical abilities, rendered him a peculiarly valuable officer, as well as an ornament to his Profession. As a colleague, Dr Coote was endeared to the Committee by the amiability of his temper and the perfect integrity of his character. And in thus recording the personal attachment which was universally felt for him, the Committee are called upon to add the expression of their belief that the fatal event which they now deplore was hastened by his conscientious perseverance in the discharge of duties far beyond his strength."

That this resolution expresses a very general feeling we are sure; and we know that our departed friend was held in the very highest esteem by the students under his tuition. With their teacher they have also lost a kind-hearted and warm friend; and the promise which he gave of future greatness makes his loss one which the Profession may lament.—'Medical Times and Gazette.'

JAMES HOWELL, ESQ., M.R.C.S.

The recent death of this gentleman, in his seventieth year, has removed from amongst us one who by his talents and influence, and especially by his high tone of professional conduct and feeling, was well worthy of the intimacy he enjoyed through life with most of the leading members of our profession in London and its vicinity.

Mr Howell became a member of the College of Surgeons in 1812, and commenced practice in Wandsworth, influenced to this step by the advice of Dr Tape, of Staines, and Mr Ives, of Chertsey. In 1814 he married the daughter of the latter gentleman; of the children of which marriage, several (including two sons in the Medical Profession) survive him. From this date to that of his death he continued to practise here, beloved and honoured, it may truly be said, by his numerous patients, and grateful poor of the neighbourhood, and the leading professional men of his day, with whom his practice necessarily brought him into a frequent contact, which his worth and manner made the prelude to friendship.

Although he contributed little to the literature of his profession, his great ability was well known to his friends, who found him, on points of importance, considerably in advance of his day. From a very early period he successfully combined the non-restraint system in the treatment of insanity with the use of a liberal diet and opium. The abuse of purgatives he also steadily resisted at all risks to himself; and there is one prominent member of the profession still alive who probably owes his life to the sagacity of Mr Howell in this respect. His success, in the more conventional meaning of the word, was early and decisive.

In 1857 his health began to fail; and he underwent an attack of fever, for which he was attended by Dr Bright and Dr Brinton. In 1858 he was seized with symptoms closely resembling those of whooping-cough, which gradually undermined his constitution. He died at his residence in Wandsworth on the 26th of September last.

Births, Marriages, and Deaths.

BIRTHS.

CREEGEN.—November 7, at Plough road, Rotherhithe, the wife of James Joseph Creegen, M.D., of a daughter.

MARLEY.—November 17, at Bromyard, Herefordshire, the wife of Richard Marley, Esq., M.R.C.S., L.A.S., of a son.

THURNALL.—November 6, at Bedford, the wife of W. Thurnall, Esq., M.R.C.S., of a daughter.

MARRIAGE.

GARNER—BIRNEY.—November 1, at Bright, William H. Garner, M.D., to Helen Cordelia, second daughter of J. Birney, Esq., of Oakley Park, Co. Down.

DEATHS.

BOWDEN.—October 28, Samuel William Bowden, of Brixham, Devonshire, M.R.C.S. Eng., L.S.A. Lond., Admiralty Surgeon and Agent, aged 52.

BURMAN.—November 4, at Wisbech, of apoplexy, Smith Burman, M.D. Edin., aged 52.

COOTE.—November 13, Charles Thomas Coote, M.D. Oxon, F.R.C.P. Lond., of Gloucester place, Hyde park, aged 36.

FRENCH.—November 22, at Cambridge Heath, James French, Esq., M.R.C.S.E., aged 76.

HALLS.—November 6, on board the Peninsular and Oriental Company's steamer 'Ceylon,' John Jas. Halls, Esq., B.A. Cantab., F.R.C.S., Assistant-Surgeon in H.M.'s Bengal Army, Surgeon at the civil station of Arrah during the siege of that place in 1857.

HART.—November 1, in Northumberland square, North Shields, William Hart, M.R.C.S. Eng., L.S.A. Lond., aged 43.

LAMONT.—November 11, Æneas Lamont, of Belfast, F.R.C.S. Ireland.

LUDLOW.—At D'Urban, Port Natal, South Africa, William Henry Ludlow, formerly of Leire, near Lutterworth, Leicestershire, aged 28.

MOLLOY.—November 14, at Hounslow, Middlesex, Robert Molloy, M.D., M.R.C.S. Eng., L.S.A. Lond., aged 45.

PEMELL.—November 13, at Canterbury, Peter Pemell, M.R.C.S. Eng., L.S.A. Lond.

PRICE.—November 13, William Price, of Portsmouth, M.R.C.S. Eng., aged 77.

PURTON.—Recently, Astley Purton, of Alcester, Warwickshire, M.D. Edin., M.R.C.S. Eng., aged 48.

RADCLIFFE.—November 5, Samuel Radcliffe, of Leeds, M.R.C.S. Eng., L.S.A. Lond., aged 53.

SCAIFE.—November 4, suddenly, William Scaife, of Kinkerry hill, Bewcastle, Cumberland.

SEIFFER.—August 26, at Greenock Creek, South Australia, A. Seiffer, M.D., aged 32.

STACEY.—November 15, Edmund Hills Stacey, of Carmarthen, M.R.C.S. Eng., L.S.A. Lond., aged 65.

TAYLOR.—October 30, at Tamworth, Joseph Taylor, late of Appleby, Leicestershire, M.R.C.S. Eng., aged 69.

THOMPSON.—November 8, Henry Thompson, of Baptist Mills, Bristol, (in practice prior to 1815,) Surgeon in the Army, aged 75.

THOMPSON.—October 31, John Thompson, of Blanchland, Riding Mill, Northumberland, L.S.A. Lond.

TURNER.—November 11, Richard Turner, of Lewes, Sussex, M.R.C.S. Eng., L.S.A. Lond., aged 61.

TWEDDELL.—November 14, at Hartley Wintney, Hants, Fenwick Martin Tweddell.

WALL.—October 27, Dr Wall, late of Dunmanway, Cork, aged 39.

WILSON.—November 8, John Grant Wilson, of Clifton, M.R.C.S. Eng., L.S.A. Lond., late Senior Surgeon to the Bristol General Hospital, aged 63.

YELLOW FEVER AT BELIZE.—H.M.S. "Icarus" has arrived at Jamaica from Belize, Honduras, having lost in that place, from yellow fever, the second lieutenant, two assistant-surgeons, master, captain's clerk, and thirty men. Many of the crew also were very ill on her arrival in Jamaica. They were all conveyed to the hospital, since which no deaths have occurred.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 15th inst.:—Henry Joseph Altmann, Islington; Frank Harvey Browne, Stowe Maries; Alfred Frederick Strafford Clarke, Gordon square; Branthwayte Beevor Ford, Longton, Staffordshire; Henry Goodall, Madras; Edward Buller Hicks, Greenhithe; George Augustus Hicks, Torquay, Devon; William Kennethmant Ironside, N.B.; Felix William Isherwood, Clitheroe, Lancashire; John Sampson Levis, Skibbereen; Samuel Lloyd, Smethwick, near Birmingham; George Valentine Theodore Manly, Free Town, Sierra Leone; John March, Hounslow; Richard Henry Milson, London; Theodore Orton, Littlebourne; William Henry O'Toole, Dublin; William Pitt, Willenhall; Thomas Savage, Wolverhampton; Edward Julian Sharood, Brighton; Charles Walls, Boothby, Spilsby; Edward Parker Young, Delamere crescent; George Edmund Young, Mechlin.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, the 15th inst.:—Charles James Bracey, Birmingham; Francis Mark Cann, Exeter, Devon; Francis William Gibson, Bath; Thomas Fitzherbert Snow, Box, Wilts; John Tanner, Tetbury, Gloucestershire. The following gentlemen also on the same day passed their First Examination:—Richard Henry Dawson, Broxholme, Lincolnshire; John Harvey, Birmingham; James Fenton Stamper, Haverfordwest. For an Assistant:—George Samuel Hodgson, London street, Greenwich. The names of gentlemen who passed the Special Preliminary Examination in Arts on Tuesday and Wednesday, the 20th and 21st inst.:—Frederick William Adams, Bristol; George Corney Birt, Brighton; T. H. Brocklehurst, Hyde; Isaac Thomas Bridgman, Saville row, Walworth; Christopher William Calthrop, Withern Alford; Frederick Chabot, Camberwell; Henry G. Dusautoy, Southampton; W. H. Harding, Aylesbury; William Brown Holderness, 12, Park street, Windsor; William John Land, Aylesbeare, Devon; F. M. Mackenzie, Tiverton; Francis M. Pemberton, York House, Chertsey; Charles John Pyle, Amesbury, Wilts; Henry Rayner, Sutton Valence, Kent; R. H. Sanderson, Wellingboro'; Reginald P. Simpson, Norwich; Henry Weekes, Brompton, Kent; William Wilks, Ashford; Eyton O. Williams, 39, Keppel street; Robert Wood, Uttoxeter.

APPOINTMENTS.—Christopher Heath, Esq., F.R.C.S., has been appointed Surgeon to the West of London Hospital, Hammersmith. Dr Thomas Chaplin has been appointed Physician to the English Hospital for Jews at Jerusalem. Mr George Lewis Cooper, F.R.C.S., Surgeon to the Bloomsbury Dispensary, and one of the Surgeons to the National Vaccine Establishment, has been nominated by the College of Surgeons as a Recognised Teacher of Vaccination, and appointed by the Council of University College to instruct the Students of the Medical School in Vaccination, according to the new regulations: Vaccine Station, 3 Caledonian road, King's cross. Edwin Benjamin Gray, M.B. Oxon, M.R.C.S. and L.S.A. Lond., House-Surgeon to the Radcliffe Infirmary, Oxford, was unanimously elected Physician to that Institution on November 15, 1860, in the room of Dr Rolleston, resigned. J. H. B. Macleod, M.D., has been elected Professor of Surgery in St Andrew's University, Glasgow.

TESTIMONIAL.—On the 15th inst., the inhabitants of Hartley Wintney, Hants, and adjoining parishes, presented a handsome silver tea and coffee service, together with a ring and set of shirt-studs, to Dr Foster, on his leaving the neighbourhood. Dr Foster has been in practice at Hartley Wintney for upwards of seventeen years, during which time he has gained, by reason of his professional skill and unremitting attention to the sick, the affection and gratitude of all classes. The testimonial is intended as a slight mark of the esteem in which he is held, and bears the simple but appropriate inscription—"To Dr Foster, from his grateful Patients."

PRESENTATION.—Dr J. T. H. Dunn, of 7 Carton place, Westbourne park, after six years' practice in the town of Whitstable, both as a General Practitioner and as Surgeon to this district of Coast Guard, having removed to London, the inhabitants, wishing to mark their sense of his worth and their regret at losing him, have presented him with a handsomely-embossed Silver Tankard lined with gold, bearing the following inscription:—"Presented to J. T. H. Dunn, Esq., M.D., by his Friends at Whitstable, as a mark of the esteem and respect in which he was held both in his professional and private character during his residence among them. Nov. 12th, 1860."

LUNACY STATISTICS.—The following very interesting statistical facts concerning English Lunatic Asylums have lately been published by Dr Tuke:—There are 31,957 persons legally certified as of unsound mind; it may, therefore, be calculated that of the adult population more than 1 in every 300 is afflicted with mental derangement. The question as to their treatment is one of great public interest. From the returns in the 14th Report of the Commissioners in Lunacy it is demonstrated that private asylums, conducted by resident Physicians, take the highest place as curative institutions, and that the rate of mortality in them is less than in any other asylum of the same description. The following results are taken from the tables given by Dr Tuke, and show the comparative advantage of 151 establishments devoted to the treatment of the insane:—

	Per cent. of cures.	Per cent. of deaths.
60 Private asylums with Resident Physicians	38·6	4·3
30 Ditto without Medical Residents	36·	4·1
20 Ditto receiving paupers	34·	7·7
41 County and borough asylums	34·	7·7

It is satisfactory to find that in some of the private asylums cures amount to more than 50 per cent. of the admissions. The importance of prompt medical treatment is shown by the recovery of nearly 80 per cent. of the cases admitted under medical care during the first three months of the malady.

PROGRESS OF THE MAIN DRAINAGE OF LONDON.—The engineer of the Metropolitan Board of Works reports that the Southern Outfall Sewer, which was commenced in the April of the present year, and is to be completed within two years from that period, will receive the contents of the High-level Sewer, at Deptford Creek, by gravitation, and the contents of the Low-level Sewer through the Deptford pumping-engines; and will convey the sewage of the whole of the southern drainage through Greenwich, under Woolwich, and across the Erith marshes to Halfway Reach in the Thames, at a point about twelve miles below London bridge. It will here be raised by pumping-engines into reservoirs, and discharged into the bottom of the river during the first two hours of the ebb-tide only; so that whilst it will there be diluted by about a hundred times greater volume of water than at present, it will also be carried by the ebb-tide to a point twenty-four miles below London bridge. The length of sewer from Deptford to the outfall is 7¼ miles; it is 11ft. 6in. in diameter, and its fall is 2ft. per mile. This work has been commenced. The tunnel under Woolwich is about one mile in length, and varies from 45ft. to 75ft. in depth. At the east end of Woolwich the cutting is through sand, and at the west end through chalk. The miners are working night and day.

A FALSE CHARGE.—At the Marlborough-street Police Court, on the 15th inst., a parochial medical officer was charged with an assault and indecent conduct towards a young woman, a servant out of place. When the evidence had been given, Mr Tyrwhitt said, these charges were easily made. It was necessary, in going into the evidence, that great particularity should be insisted on, and great attention had been given to this case. Medical men, and surgeons more than any men, were exposed to such accusations. He was of opinion that the present charge against the defendant had not been made out, and he should certainly not commit him, but leave the complainant to proceed, if she should think fit, by indictment at the sessions. He did not believe the charge, and should therefore, so far as this court was concerned, discharge the defendant.

DISEASES OF THE UTERUS.—Although it is a matter of common observation that uterine diseases have never been more prevalent than during the last few years, yet we were scarcely prepared to learn that they often ran a fatal course in men. Nevertheless, according to the Registrar-

General's Twenty-first Annual Report, "Disease of the Uterus, &c.," was the cause of death in no less than fifty-three males in England during the year 1858. In London alone there were four fatal cases—a rather extraordinary fact, inasmuch as neither man nor boy died of ovarian dropsy! Would it not be advisable to start a special hospital for these obscure affections in the male sex?

ANOTHER VICTIM TO PROFESSIONAL COURAGE.—M. Desprès, Surgeon to the Bicêtre Asylum near Paris (for the insane and likewise for aged men), has just died, in the vigour of manhood, from a contagious disease caught whilst attending one of his pupils affected with the complaint. M. Desprès is universally regretted.

A NEW NATURAL HISTORY REVIEW is announced, in which Dr Carpenter, Mr Busk, Professor Huxley, and others will assume a part.

THE WOUNDED GARIBALDIANS.—The Ladies' Garibaldian Benevolent Association have just remitted to General Garibaldi a further sum of 500*l.* for the use of the sick and wounded volunteers of his army.

FEVER IN HUNGARY.—In the country of Arad, in Hungary, eight-tenths of the population have, this autumn, been attacked with intermittent fever; but few deaths have taken place.

PROPOSED DISPENSARY AT ALDERSHOTT.—Not merely in the spirit of charity, but of prudence and economy, the attempt now being made to organise a dispensary at Aldershott is one deserving every co-operation. The condition of the poor wretches who swarm round the camp has been described to us as most horrible, and in endeavouring to give them the relief likely to be afforded by an institution such as that which is projected, its originators are exercising charity in a most discriminating way. Wretched outcasts as they may be, they surely do not merit the heartrending sufferings they undergo, ending sometimes in such a death as humanity must shudder to contemplate. We trust the Government will not withhold its assistance, as the indirect operation of the institution must be attended with results most beneficial to the sanitary condition of the soldier, and of course to the public finances, which suffer in proportion as they become unfit for service by disease. The Rev. J. Dennett, incumbent of Aldershott, and Messrs Mangles' Bank, Aldershott, receive subscriptions. —'Army and Navy Gazette.'

THE SKELETON OF "ECLIPSE."—Professor Gamgee has secured for the New Veterinary College the bones of this noble animal, at the cost of one hundred guineas. The skeleton has for nearly seventy years been in the possession of the illustrious Bracy Clark. Its high intrinsic value depends on "Eclipse" being regarded, from his great fleetness and power of endurance, as the finest type of a blood-horse ever born. From the blood of this horse are derived all the most renowned performers of the present time; and it was from the skill and talent displayed by Sainbel in dissecting this horse, and publishing a memoir on his unrivalled proportions, that ensured him the support in founding the Royal Veterinary College of London. Large sums have been offered for this remarkable skeleton, and, amongst others, sixty-guineas by the Royal College of Surgeons of England. Mr Bracy Clark, the first student of the London College, received the bones from Sainbel himself, and has justly said of them that "they may be securely referred to as an unexceptionable model on which to calculate speed in horses."

JOURNEYMEN BAKERS.—What is the baker's state of health? What is his chance of life? What ought he to do in his particular circumstances? The tables of Friendly Societies tell us that bakers stand fifth on their lists. There are four trades that are more sickly, and nineteen that are less so. During the period of relief in sickness—in other words, from 20 to 70 years of age—the bakers claim for 178 weeks of sickness; that is, nearly three years and a half of such illness as renders them unable to work. The very most burdensome class is that of the potters, who are ill for 333 weeks of the same period; and the best are the clerks and schoolmasters, who claim for 48 weeks, or less than a year. But these figures do not show the full strength of the case. The clerks and schoolmasters are, in large proportion, living at nearly or quite the end of the term; whereas the potters were, for the most part, dead in a few years from the outset, and the bakers disappear, on an average, before the middle of the term. Those who live for ten years of the time have fewer weeks of chargeable sickness, and those who live 30 have more; and the computation made is the average; but if the term were not from 20 to 70, but from 20 to 50, the bad case of the potters and bakers would be seen to be very much worse than it now appears.—'Once a Week.'

USELESS VIVISECTIONS.—The 'Moniteur des Sciences Médicales' makes the following lame reply to charges which have been made of the wanton cruelty in practising operations on living animals at the French Veterinary Schools:—"Our learned friend [the Editor of the 'Cosmos,' who had reproduced the English charges] must know, better than we can tell him, that exaggeration is a defect in anything, and it is a pity that he did not declare to his London and Dublin correspondents that their zeal carries them too far. Personally, we deplore as much as any one can useless cruelties, whether exercised on man or beast; but we cannot admit that our excellent friends at Alfort and elsewhere are transformed in Cabochés or Caligulas, merely because they practise their pupils on living animals, *which is, however, unfortunately true.* But we cannot allow ourselves to decide that they are able to do without this procedure of instruction, and must confine ourselves to expressing a wish that they may be able to do so, and we beg our learned friend to transmit our statement to his honourable zoophitist correspondents"!

DURHAM UNIVERSITY.—Mr Albert O. Haslewood has obtained the Medical Scholarship at this University, in connection with the Newcastle College of Medicine.

NOMINATION OF M. GENDRIN TO THE LEGION OF HONOUR.—There is a piece of news which cannot fail to astonish not a little the Medical public in France, and especially that of foreign countries. After thirty years of the most remarkable clinical teaching, after the publication of works no less remarkable, and after thirty years' service in the Hospitals, M. Gendrin was not a member of the Legion of Honour, of which he has just, indeed, been appointed Chevalier. It is true that his name is known in the two worlds, which is, indeed, a tolerable consolation for the loss of a ribbon,—so considerable a consolation, indeed, that we really think that, had we been in M. Gendrin's place, we should have contented ourselves with it for the rest of life.—'Moniteur des Sciences.'

STREET ACCIDENTS IN PARIS.—We gave lately a return of the number of deaths in the city of London from street accidents. A Paris letter says that, "according to statistical returns prepared by M. Poursageand, a distinguished geometrician, the too great number of carriages which perambulate Paris cause the death annually of 700 persons, and wound 5000. Woe to the deaf and the blind! woe to the absent man! In some public places coachmen advance on the pedestrian from five or six quarters simultaneously, and when they do not drive over him they insult him, and he deems himself fortunate to escape with insult. It follows from M. Poursageaud's calculation that carriages in Paris kill and wound more people than all the railways in Europe. They kill and wound more people than the four million of carriages in the rest of France. The proportion between the victims in the provinces and in Paris is 1 in the provinces to 400 in Paris."

DEATH FROM LOCKJAW.—Mr Wakely, the coroner, held an inquest last week at the Rising Sun Tavern, Euston road, on the body of Mrs Frances Margaret Moore, aged forty-two, housekeeper at the General Dispensary, 126 Euston road, whose death took place on last Wednesday week from lockjaw under very remarkable circumstances. Dr Semple, of Tavistock square, stated that on Sunday, the 11th inst., he attended Mrs Moore, whom he found suffering from lockjaw. She was very ill, and could speak at intervals, but with great difficulty. He was informed in her presence, and to which she assented, that it was a lockjaw caused by a dental operation, apparently properly performed, by a professional dentist, two days previous, of snipping two molar teeth, for the purpose of fixing artificial teeth, which she was in the habit of wearing. The lockjaw continued until the Wednesday morning, when she died. From the Sunday to the Wednesday she suffered severely, and during a greater part of that period she was kept under the influence of chloroform. The sole cause of death was unquestionably from lockjaw. Other witnesses deposed that up to very recently she had been addicted to rather intemperate habits, and that every effort on the present occasion was exerted to save her life. The jury, the medical witness, and the coroner expressed their astonishment at the remarkable death. The two latter gentlemen added that habits of intemperance or unsoundness of mind had probably tended to promote the lockjaw. The following verdict was recorded: "That deceased died from lockjaw, occasioned from natural causes, by the snapping of the crown of two teeth."

APPOINTMENTS FOR THE WEEK.

Wednesday, November 28.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—Mr F. T. Buckland, M.A., "On the Acclimatization of Animals," 8 p.m.

HUNTERIAN SOCIETY.—8 p.m.

Thursday, November 29.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Surgical Home.—2 p.m.

KING'S COLLEGE MEDICAL SOCIETY.—Mr Earle, "On Apnœa Neonatorum."

Friday, November 30.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, December 1.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—Clinical Lecture on "Epilepsy and Paralysis," by Dr Brown-Séquard, 3½ p.m.

Monday, December 3.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.

MEDICAL SOCIETY OF LONDON.—8½ p.m.

ODONTOLOGICAL SOCIETY OF LONDON.—8 p.m.

Tuesday, December 4.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

PATHOLOGICAL SOCIETY.—8½ p.m.

BOOKS RECEIVED FOR REVIEW.

Vestiges of Creation. Eleventh Edition. London: John Churchill.

Transactions of the Pathological Society of London, Vol. XI.

The Medical Vocabulary. By Robert Fowler, M.D. London: Henry Renshaw.

NOTICES TO CORRESPONDENTS.

Mr SWINDELL.—Received.

Mr JENKINS.—Note, with enclosures, received.

OMEGA.—The advertisement is one of the most disgraceful things of the kind we have seen for a long time. We have commented upon it elsewhere.

A SUBSCRIBER.—Neuralgia is a vague term, including a variety of diseases: it may, therefore, have a variety of causes. We believe that most cases of neuralgia have their origin in atmospheric changes and disorders of the stomach. A change in the barometric condition will readily induce neuralgia in persons liable to it; but then it is necessary to define neuralgia. Tonics, regimen, and change of air are the best remedial agents.

Mr W. S.—1st. Yes.—2nd. Yes.

L.R.C.P. EDIN.—A Licentiate may call himself "Doctor," the Medical Act notwithstanding. He cannot use the letters M.D., or style himself Doctor of Medicine,—at least, we do not think that he could honourably do so, for it is difficult to say how far the law would prevent him. Medical law is in a greater muddle than it ever was, thanks to the Medical Act.

M.D.—No.

Mr BAKER is thanked for his communication.

Dr RIDOE.—Received.

Mr OSBORNE.—It shall be forwarded.

H. B.—The dispensing of medicines would render you ineligible for admission into the London College of Physicians. It is too pure a body to endure the smell of rose-water.

A SUBSCRIBER (Coventry).—It will be too late.

CELSUS.—The subscription is one guinea per annum. You should write to the Secretary.

M.R.C.S. & L.A.C.—1st. You would be received at St Andrew's. Write to Dr Day.—2nd. Not in law.—3rd.—See our article in this Number.

ERIENSIS.—We hope that Dr Wall's family will be kept from want by the liberality of the Profession. He was the victim of a ruthless law.

Dr WILLIAMS.—The Publisher will write to you.

Dr B. W.—Enclosures received.

Mr FERGUSSON is thanked.

Mr B. KING.—1st. Yes.—2nd. No.—3rd. Churchill.

AN AUTHOR.—Mr Churchill has refused to sell the works of Dr Jordan, the Skin Doctor. This is the best answer to your inquiry.

Dr DUNN.—Received.

Mr JOHN GRANT SMITH.—Note with enclosure received as we were going to press. We will take an opportunity of looking through the pamphlet.

Loan, Discount, and Deposit BANK.

Established 1849.—145 Blackfriars road. S.

DEPOSITS.—Sums of £1 and upwards received, bearing interest at from 5 to 10 per cent., withdrawable as per agreement.

DISCOUNT.—Approved Trade Bills negotiated at two days' notice.

LOANS.—From £6 to £200, repayable by easy instalments, on approved Personal Security, Bills of Sale, Mortgages, Life Policies or otherwise.

Prospectuses, and every Information, may be obtained by letter or personal application.

EDWARD LEWIS, Manager.

145 BLACKFRIARS ROAD, S.

Liquor Castanea Equina.—

Messrs. REW and Co. respectfully solicit the attention of the Profession to this Preparation of the Horse-Chesnut; taken internally for Rheumatic Gout and Rheumatism, it is a safe, agreeable, and most efficacious remedy.

Dose, two to four drachms. Price 12s. per pound.

The Oil of Horse-Chesnuts applied externally for enlarged and stiff joints, acute or inflammatory pain of any kind, gives almost immediate relief.

These genuine Preparations of the Horse-Chesnut are prepared only by REW and CO.

LITHIA WATER, LITHIA POTASH, and LITHIA AMMONIA WATER. These Waters are prepared according to the Instructions of Dr Garrod, and each bottle is guaranteed to contain the proper proportion of Lithia. 5s. per doz.

R. M. REW and CO., Operative Chemists, 282 Regent street, London.

Bass's East India Pale Ale,

BARCLAY'S PORTER AND STOUT,

In 18-gallon Casks, Bottles, Half-Bottles, and Imperial Pints.

Also DEVONSHIRE CIDER.

BERRY BROS. and Co.,

3 St James's street, London.

Kinahan's LL Whisky v.

COGNAC BRANDY.

This celebrated old IRISH WHISKY rivals the finest French brandy. It is pure, mild, mellow, delicious, and very wholesome. Sold in bottles, 3s. 6d. each, at most of the respectable retail houses in London; by the appointed agents in the principal towns in England; or, wholesale, at 8, Great Windmill street, Haymarket.—Observe the red seal, pink label, and cork branded "Kinahan's LL Whisky."

WATER BEDS AND CUSHIONS.

A Preventive against Bed

Sores, &c. Bed Sheets, Air Cushions, and all necessary Utensils for Invalids.

BENHAM and Co.,

Practical India-rubber Workers, 118 Oxford Street, W.

Child's Patent Electro-Gal-

VANIC and METALLIC BRUSHES, for all Neuralgic and Rheumatic affections, preventing the hair becoming grey; no trouble in use, effect certain.

CAUTION.—Be sure to see that "Child's patent" is on each brush. Parties have been much disappointed by buying inferior brushes, which not only destroy by breaking the hair, but are useless for the purpose of restoring and preserving it.—Sold by all chemists, perfumers, etc.

Manufactory, 21 PROVIDENCE ROW, FINSBURY.

S. Bowles (late Windsor and

Co.), PHIAL and BOTTLE MERCHANT, Dealer in Druggists' Sundries, &c., 6 James street, Covent garden, W.C. The cheapest house in London for every description of MEDICAL GLASS of the best quality.

Samples and prices forwarded free on application.

The Pulvis Jacobi Verus,

prepared by WILLAM HOOPER, 24 Russell street, Covent garden, from its identity with the more costly preparations and its acknowledged efficacy as an Antimonial, merits the patronage of those Gentlemen who have not hitherto included Pulvis Jacobi in their daily Materia Medica. An extensive continuous demand, for Public Institutions, has satisfactorily verified the ancient character of this medicine. It is sold in 1 oz. and 4 oz. bottles, at 2s. 9d. and 10s. 6d.; and in packets for transmission by post.

PULVIS JACOBI *VER.*, NEWBERY'S.

To the Medical Profession of Great Britain and Ireland.

GENTLEMEN,—We beg to call your attention to the following extract from a Paper by the late John Cheyne, M.D., F.R.S.E., M.R.I.A., Physician to the Hardwicke Fever Hospital, Dublin, and Physician-General to His late Majesty's Forces in Ireland, &c., &c., contained in "*the Dublin Hospital Reports*," *vol.* I, *p.* 320.

"The following very simple method of "exhibiting JAMES'S POWDER, in cases "of undue determindtion of blood to the head, "is that which I have generally pursued. The "patient is made to begin with a very moderate "dose, not more than two grains at bedtime, "and to increase the dose by half-a-grain every "night, until some sensible effect is produced "upon the stomach, bowels, or skin. Should "the stomach be affected with sickness, the dose "must be lessened, by one grain on the following "night. *By the addition of a little rhubarb "to it, a larger quantity of* JAMES'S "POWDER *may be administered than the "stomach could otherwise bear.* If the skin "is softened, or the bowels affected, the dose "should not further be increased, but it must be "repeated every night for a considerable length "of time: in several instances I have known "eighteen or twenty grains taken for a consi-"derable period without any inconvenience."

To secure the dispensing of the *original* preparation, which, for 114 years, has been sold by the house of Newbery and Sons, in St. Paul's Churchyard, it is necessary to prescribe it as "PULVIS JACOBI VER., NEWBERY'S," otherwise another article (wanting in the best properties, and recommended to be given in a different code of dose, *though called by the same name*) may be substituted for the original medicine.

This substitution must bring disappointment, and of course lead Practitioners to give up prescribing Dr. James's Powder altogether, or to regard it as a preparation on which no dependance can be placed.

FRANCIS NEWBERY AND SONS.
45, St. Paul's Churchyard, London.

Prices for Dispensing ½ oz. Bottle 3*s.* 4*d.*, 1 oz. 9*s.* Usual Discount to the Profession.

GAS STOVES,

GASELIERS, AND GAS FITTINGS OF ALL KINDS, FOR CHEMISTS, &c.

H. MATHER,
18 HIGH HOLBORN.

TEETH WITHOUT SPRINGS,

BY HER MAJESTY'S ROYAL LETTERS PATENT.

Newly-invented Applica-

TION of PREPARED INDIA-RUBBER in the construction of Artificial Teeth, Gums, and Palates.

MR EPHRAIM MOSELY,
SURGEON-DENTIST, 9 GROSVENOR STREET,

SOLE INVENTOR AND PATENTEE.

A new, original, and invaluable invention, consisting in the adaption, with the most absolute perfection and success, of CHEMICALLY-PREPARED INDIA-RUBBER, in lieu of the gold or bone frame. The extraordinary results of this application may be briefly noted in a few of their most prominent features:—All sharp edges are avoided; no springs, wires, or fastenings, are required; a greatly-increased freedom of suction is supplied; a natural elasticity, hitherto wholly unattainable, and a fit perfected with the most unerring accuracy, are secured; while, from the softness and flexibility of the agent employed, the greatest support is given to the adjoining teeth when loose, or rendered tender by the absorption of the gums. The acids of the mouth exert no agency on the Chemically-prepared India-rubber, and as it is a non-conductor, fluids of any temperature may be retained in the mouth, all unpleasantness of smell or taste being at the same time wholly provided against by the peculiar nature of its preparation. Teeth filled with gold, and Mr Ephraim Mosely's Cement, the only stopping that will not become discoloured, particularly recommended for front teeth.—9 Grosvenor street (W), London; 14 Gay street, Bath; 10 Eldon square, Newcastle-on-Tyne.

Human Osteology

from France.—RAGINEL, 38 Ludgate hill, City, E.C., London. Patronised by the Royal College of Surgeons of England. Illustrated Osteology on the bones themselves. Very large stock on the lowest possible terms. Disarticulated Skulls, in twenty-two pieces, in box. All the bones of the disarticulated skulls will be fitted in right order in the presence of the purchaser, so as to show that every bone of each set belongs to the same skull; it will be the same for all other disarticulated pieces. Skulls with Sections. Hands and Feet on cat-gut. Disarticulated Skeletons, quite complete, with the Skull same body. Articulated Male Skeletons, the bones very well marked.

STUDENT'S CASE OF OSTEOLOGY, COMPLETE.

Splendid Pieces for Lecturers and Museums.

Elastic Supporting Fabrics,

of very superior textures, for Varicose Veins, Accouchement, Spinal Affections, Hernia, &c. Instructions for measurement, and prices, on application to the Manufacturers, POPE and PLANTE, 4 Waterloo place, Pallmall, London, S.W.

RUPTURES. BY ROYAL LETTERS PATENT.

White's Moc-main Lever

TRUSS is allowed by upwards of 200 Medical Gentlemen to be the most effective invention in the curative treatment of HERNIA. The use of a steel spring, so often hurtful in its effects, is here avoided: a soft bandage being worn round the body, while the requisite resisting power is supplied by the MOC-MAIN PAD and PATENT LEVER, fitting with so much ease and closeness that it cannot be detected, and may be worn during sleep. A descriptive circular may be had, and the Truss (which cannot fail to fit) forwarded by post, on the circumference of the body two inches below the hips being sent to the Manufacturer,

JOHN WHITE, 228 Piccadilly, London.

Price of a Single Truss, 16s., 21s., 26s. 6d. and 31s. 6d.—Postage, 1s.

Price of a Double Truss, 31s. 6d., 42s. and 52s. 6d.—Postage, 1s. 8d.

Price of an Umbilical Truss, 42s., and 52s. 6d. Postage, 1s. 10d.

Elastic Stockings for Vari-

COSE VEINS, and all cases of Weakness and Swelling of the Legs, Sprains, &c. They are porous, light in texture, and inexpensive, and are drawn on like an ordinary Stocking. Price 3s. 6d. 7s. 6d., 10s., and 16s. each. Postage, 6d.

JOHN WHITE, MANUFACTURER,
228 Piccadilly, London.

Lateral and Angular Cur-

VATURES of the SPINE.

In calling the attention of the Profession and Public to the SUPPORTS made by them, WM. WHITING and SONS beg to state that their extensive experience (over twenty years) warrants them in asserting that the IMPROVED SUPPORT which they now manufacture will be found to be the most effectual of any in use. At the same time, they are LIGHT, COMFORTABLE TO WEAR, AND COMPLETELY INVISIBLE THROUGH THE DRESS, as experienced by the many hundreds of persons of every age and sex who are now using them.

W. W. and Sons would also invite attention to their IMPROVED EXERCISING MACHINES, SPINAL COUCHES, and their various other contrivances required in Orthopædic practice.

Manufactory, 28 High street, Camden town.

N.B.—Makers (by authority) to the Spinal Hospital, Portland road, Regent's park, founded by the late Dr Verral.

Surgical Instruments.—

J. ARNOLD continues to supply Instruments of the best workmanship at moderate prices, manufactured on the premises under his own superintendence.

J. ARNOLD, 35 and 36 West Smithfield, E.C.

Established 1819.

Chiosso's Gymnasium and

SCHOOL of ARMS, 231, EUSTON ROAD, Corner of Gower street North (near University College).

Mr ANTONIO CHIOSSO begs to draw the attention of Parents, Guardians, and all those who have the charge of Youth, to his system of Physical Education, which has proved, through experience, to be the most invaluable means of rectifying Physical Defects in the human organisation, such as Curvature of the Spine, Contraction of the Chest, general Debility of Body, &c., &c. Classes meet every hour of the day, attended personally by Mr Chiosso, from 9 A.M. till 10 P.M.

CLINICAL LECTURES.

ON DISEASES OF WOMEN.

DELIVERED AT ST THOMAS'S HOSPITAL,
BY CHARLES WALLER, M.D., Obstetric Physician to the Hospital.

(Continued from page 338.)

LECTURE IV.—GENERAL OBSERVATIONS ON DISEASES OF THE UTERUS, AND THE MODE OF EXPLORATION.

In a former lecture I directed your attention, gentlemen, to one of the various forms of uterine disease—namely, polypus of that organ. I was anxious to bring the subject before you at that time, inasmuch as there were cases in the ward which gave you the opportunity of *seeing* as well as hearing what plan should be pursued for their cure. Before we proceed any further, I think it well to make a few general remarks on diseases of the uterus and its appendages, and to point out to you our means of diagnosis. The uterus is subject to a great variety of diseases, some of a benign, others of a decidedly malignant character. It is the seat of various enlargements, differing widely in their nature. In some instances a great increase in the size of the uterus is produced by a merely congested state of its blood-vessels, giving rise to a train of symptoms which are sometimes alarming to the casual observer. Experience, however, has taught us that these cases generally end favourably. Enlargement of the womb is sometimes caused by abnormal deposit of fibrous matter, either throughout its substance, producing a uniform increase in the size of the organ without much deviation from its ordinary shape, or it may be more partial, forming masses of greater or smaller size, growing from within or from without, giving to the uterus an irregular, nodulated shape. When these proceed from the exterior, they may be distinctly felt through the abdominal parietes. Their number varies greatly. In some instances but little inconvenience is experienced, especially when the growth projects into the abdominal cavity and its size is inconsiderable; if large, it must necessarily interfere with the functions of the neighbouring parts. I have at this time recalled to my memory the case of a lady who died from obstruction in the bowels, in consequence of a large uterine tumour which prevented the passage of the fæces.

Again, you may have enlargement of the uterus as the result of conception: and where the female has an interest in deceiving the medical attendant, it is by no means easy to form a correct opinion during the early months; and if uterine tumour be complicated with pregnancy, the difficulty will be greatly increased. A very perplexing combination of this kind occurred to me a few years ago.

A lady married at the age of forty-six. The catamenial discharge, which had previously been quite regular, ceased two months after her marriage. The suppression continued for three months, when my opinion was requested; and although the general symptoms pointed to pregnancy as their cause, there were some considerations which made me give a doubtful opinion. In the first place, the age of this lady naturally suggested the probability that the period had arrived at which the cessation of the catamenia might, in the ordinary course of nature, be expected. The chief difficulty, however, arose from the following cause:—The uterus had manifestly increased in size; but it contained within its walls a diffused fibrous tumour of considerable magnitude, and its position was such that, on a vaginal examination, no portion of the sound uterus could be felt; the finger rested upon this large hard mass, so that the contents (if any) of the uterus could not be distinguished through it. In due time the movements of the fœtus dispelled all doubt. Until this had taken place, I did not commit myself by giving a decided opinion.

One circumstance, however, I would particularly call your attention to in these complicated cases; and it is this—that in pregnancy there is uniform and progressive increase of size: the uterus becomes larger from week to week, whilst, on the other hand, the growth of fibrous tumour is slow. There is often for months, or even in some cases for years, little perceptible increase.

The uterus is also the seat of ulcerations, differing in their nature, some not discoverable without the aid of the speculum, and, consequently, not understood without the use of this instrument. Of this kind I would especially mention that superficial ulceration so often met with in cases of obstinate leucorrhœa. This, if combined with much surrounding inflammation, is extremely difficult of cure; but it is not attended with danger. Again, in syphilitic ulceration of the cervix uteri, if the touch alone were employed, you would, in all probability, not be able to ascertain its precise nature; and, consequently, you could not administer the appropriate treatment.

Mode of Exploration.—The means whereby the existence and nature of diseases of the womb and its appendages may be detected are twofold—namely, by the external or the internal examination: or I should rather say, by the use of both, as, except in some cases of tumour, the external examination alone is seldom sufficient. True, there are many symptoms, both general and local, by which the seat of the disease is indicated with tolerable clearness; yet these same symptoms are present in so many different conditions of the generative organs, as to render them of little value in the diagnosis of the particular disease. Let us take for our illustration leucorrhœal discharge. This is ofttimes the result of debility of constitution, combined with a relaxed condition of the vaginal or uterine membrane; or it may be the result of an inflamnatory condition of the parts, common or specific. It is also invariably present in the more severe forms of uterine disease—such as carcinoma, &c. &c. It is sometimes the effect of sympathetic irritation, from ascarides in the rectum, or from calculus in the bladder. The same observations may also be applied to hæmorrhagic discharges: these are sometimes the result of an over-full state of the blood-vessels, and are Nature's simple remedies for the relief of plethora. At others, the opposite state of system exists. In the one, the hæmorrhage is of the active character; in the other it is passive. This is not all; for the more formidable and fatal diseases are always attended with large losses of blood, the existence of which can only be ascertained by careful examination.

External Examination.—You will bear in mind that the pelvic contents are enclosed posteriorly and laterally by a tolerably complete osseous case; whilst anteriorly they are covered by the abdominal muscles and integuments, with the exception of that shallow portion of bone, termed symphysis pubis, which is formed by the junction of the ossa innominata in front. In a female, therefore, who is naturally thin, or who has been attenuated by disease, the existence and size of a tumour may easily be ascertained by a manual examination through these integumental coverings. Sometimes its seat may also be determined—where, for example, the patient is suffering from ovarian dropsy of long standing, and the cyst has attained a large size. You will also be able to discover whether the tumour be dense and hard, or fluctuating; and whether it be comparatively free, or fixed by adhesion to the surrounding parts: whether it present one solid, large mass, definite in shape; or whether composed of a number of smaller substances, presenting an irregular, nodulated surface to the touch. Still, as a general rule, the exceptions to which are very few indeed, the information derived from an external examination is not sufficient, although it must by no means be neglected; for it not unfrequently happens that by this method alone we shall find that a *supposed* internal tumour has no existence whatever. Very many cases of this kind have come under my notice in which the tumour, so called, consisted of a large deposit of fat beneath the abdominal integuments. This I shall more particularly describe to you when I speak of the diagnosis of abdominal and pelvic tumours.

Internal Examination.—The internal examination consists either of a simple manual exploration, by *the touch*, as it is called, or, where necessary, by the use of the speculum, by means of which the diseased parts are brought into view, and thus the Practitioner is enabled to *see* the malady he is about to contend with. The former method is of little avail, unless you keep in remembrance the natural position, size, and shape of the contents of the pelvis, and the relation of each to the other. Let me, therefore, remind you that the uterus (the principal pelvic organ) is placed at the extremity of the vagina, having the bladder in front, the rectum behind, the convolutions of the intestines above, and the ovaries at its sides. Its position is somewhat oblique, the fundus being slightly inclined backwards, kept in its situation principally by the broad ligaments, which are composed of a double fold of peritoneum, proceeding from the sides of the organ to the corresponding lateral portions of the pelvis: the round ligaments, and that portion of peritoneum which is reflected from the anterior and inferior part of the bladder (sometimes called the anterior ligament), may also assist; some support is also obtained from the upper part of the vagina, which embraces the cervix uteri in an oblique direction from before backwards, at about half an inch from its anterior and lower extremity, and a few lines higher posteriorly. The uterus, thus placed and supported, is movable to a considerable extent: its situation, therefore, will be changed by any movement imparted to the abdominal viscera, such as straining at stool, or by a powerful muscular effort in attempting to lift heavy weights: and this especially happens if there be any enlargement of the uterus from any cause, whether from engorgement of the neck, or tumour, or if the ligaments be relaxed, as they always are to a certain extent for some time after delivery. From either of the above causes the womb may be forced low down in the pelvic cavity.

In examination by the touch, the size, position, and shape of the uterus, with the opening into its cavity (os uteri), may easily be ascertained; together with the existence of tumour, if such be present—the nature of such tumour, whether of extraneous growth, or morbid enlargement of natural parts.

In many cases however, the mere touch, unaided by the eye, is not sufficient; and then recourse must be had to the speculum—an instrument invented for the purpose of dilating the vagina, and bringing the os and cervix uteri within the sphere of vision. Abrasions, excoriations, and ulcerations not discoverable by the finger are thus brought into view, and the required applications easily applied to their surfaces, by means of which cases which had resisted previous treatment have been brought to a successful termination.

The use of the speculum uteri in England is of comparatively recent date. It was little known, or at any rate but little employed, before

the year 1836, when Dr Balbirnie published his work on 'Organic Diseases of the Womb.' He had just returned from France, where he had attended the practice of Messieurs Ricord, Lisfranc, and Emery. He returned to England, and determined to practise here what he had seen to be so serviceable in the hands of the Parisian Practitioners. In speaking of this new method of uterine exploration, he exclaims, with all the enthusiasm of a new convert, "We go forth the apostle of the speculum: with that instrument we stand or fall." Dr Balbirnie quotes passages from Galen, Aetius, and Paulus Ægineta, proving that they possessed a true speculum uteri, under the designation of "διοπτρα." The latter Author gives very particular directions concerning the mode of introducing it.

The instrument as then used was probably very imperfect in its construction, for it seems to have been abandoned for a time. At a later period, a great improvement was made by M. Recamier, and the speculum became a surgical instrument of acknowledged utility, and was very generally used in the Parisian Hospitals. Various alterations have been made in its shape and size: all these however, numerous though they be, may be described under two forms; the one a solid and simple tube, the other composed of different portions or blades, so arranged that on their first application they are in close contact, and indeed overlap each other, thus affording all the advantages of a simple tube as regards facility of introduction: by compressing the handles these blades may be separated from each other to a greater or less extent, as the case may require; and when so separated the dilatation is greatest at the uterine extremity, and thus the parts required to be seen are brought into view, not merely the os uteri, but the whole of that portion of the cervix which projects into the vagina, so that its condition, whether increased in size — its state of vascularity, whether inflamed or otherwise—may be distinctly seen, and in this way much valuable information may be derived which could not be obtained by the tubular instrument without subjecting your patient to much pain from its necessarily large size. I show you examples of the two forms of speculum now in use: here the tubular, of various sizes; and here, again, the branched speculum, some having two, some three, and some four branches. The latter, as recommended by M. Ricord, I prefer to either of the others. The speculum I now exhibit is used by many: it is, as you see, made of glass, coated with metallic foil, and then covered over with a solution of india-rubber: the interior is thus made a highly-reflecting surface, and the consequence is this: so much white light is thrown upon the parts exposed to the eye, that their real colour cannot be discovered, and although the utero-vaginal membrane may be vividly inflamed, presenting, under the ordinary light of a candle, a bright red appearance, yet, in consequence of the reflection of the rays from this mirror, the naturally red colour is destroyed, and the membrane appears comparatively pale, and hence the real state of the parts will not be satisfactorily ascertained. This, gentlemen, is not a fanciful or theoretical objection; I have tested the value of the two instruments, where I wish you to test every opinion and recommendation given you in the course of practical instruction delivered within the walls of this hospital—namely, at the bed-side of the patient. I have used both specula in the same case, introducing one immediately after the other: the result was, that the appearance presented to the eye was totally different; the one exhibiting the vaginal membrane in a state of active inflammation, marked by its blood-red colour; whilst with the other this indication of inflammatory action was not visble.

We shall continue the subject in our next lecture.

THE PARASITICAL DISEASES OF THE HEAD AND FACE.

By GEORGE ROSS, Esq., M.D., &c.,

Author of the 'Constitutional Relations of Diseases of the Skin.'

No. II.

SCALL HEAD,—PORRIGO FAVOSA.

Local Symptoms.—This disease is characterised by a number of bright yellow spots, small in size, scarcely raised above the skin, and cupped in the centre, from which a hair usually springs. In a short time, a crust is formed, retaining all the characters of the original eruption, and surrounded by a reddish base. This crust adheres firmly to the skin; but it may be picked off; and when removed, its under surface is found to be convex, and resting upon a depressed portion of the scalp, which is smooth and shining. It spreads from its outer margin, and attains the diameter of a split pea. When it coalesces with a neighbouring crust, the united crusts lose, in some degree, their umbilicated character and their uniform roundness of outline. Sometimes the entire scalp becomes thus covered with incrustation. If the disease be of old standing and obstinate, pustules may form, and subsequently ulcerations, attended with a foul sanious discharge. These ulcerations frequently destroy the scalp itself, and kill the roots of the hair. The accompanying discharge also scabs, and renders the discrimination of the true favus crust sometimes difficult. In bad pustular cases without ulceration, the discharge is only occasional, and soon dries.

From the earliest period of the disease, the hair is loosened and easily removed. As the disease advances, it withers, breaks, loses its proper colour, and falls out; and, at length, patches of baldness result.

In the early stages, scall head is not very troublesome to the patient; but in its course it is accompanied with heat and itching, and the crusts emit a peculiar faint and offensive odour, like that of mice or cats' urine. If the patient be neglected, lice swarm under the scabs and infest the head, and the little sufferer becomes a pitiable and loathsome object. The entire surface of the scalp is usually covered with a whitish scurf in all cases.

The crust of favus, so called from its resemblance to a honeycomb, is formed beneath the epidermis, which in an altered state constitutes, in fact, its upper surface; its middle portion is composed of a powdery mass, of a lighter colour than the upper surface; the under portion of the crust is much firmer in texture, and of a "honey-yellow" colour.

Constitutional Symptoms. — Scall head is sometimes a most obstinate complaint, owing to its being associated with a scrofulous constitution. It may not happen in the earliest period of the disorder that any other obvious sign of tuberculosis may exist than that presented by the disease itself; but if it continue for any length of time, the glands of the neck become inflamed. Though they enlarge considerably, they seldom suppurate. The child's flesh feels flabby; its skin is etiolated, harsh, and dusky; its limbs look shrunken, its abdomen swells, its general bodily development is stunted, and its mental faculties gradually suffer a serious and, perhaps, irremediable impairment. Idiocy is not an uncommon attendant of this disease in its severest form. It is highly probable that this unhappy sequence of constitutional evils may be prevented by an early arrest of the disease; for in mild attacks this impoverishment of the constitution is not apparent.

It is obvious that the constant irritation causes the submaxillary glands to swell: these, by long-continued pressure upon the blood-vessels of the neck, prevent a due supply of healthy blood to the brain, which is, therefore, arrested in its development; and the subsequent degeneracy of the constitution is easily explained by the deficiency of nervous power thus induced.

It must not, however, be forgotten that there is a scrofulous diathesis to begin with as a starting-point of the disease; and my observation in these diseases has led me to conclude that some portion of the fluid that exudes from the scalp is actually reabsorbed, and thus increases the vitiation of the blood. In a paper I read two years ago at a Meeting of the Medical Society of London, I laid down the proposition of the absorption of the lymph from the pock as an explanation of the mode in which the system becomes infected in vaccination: I believe it holds good also of small-pox, and of all diseases characterised by impure secretions. In short, these diseased secretions are not simply eliminative; they are reabsorbed into the system, in the same way that natural and healthy secretions are—and even the excretions also, under favourable circumstances. This is not the place to enlarge upon this generalisation; but I may say that it explains to the satisfaction of my mind much that it is obscure in the mode of action of specific diseases.

These observations show the momentous importance of a judicious treatment of scall head in its early stages. Every day of the continuance of the affection tends to aggravate the constitutional malady, until at length the bodily health may be so much deteriorated that the cure of the eruption becomes a matter of the most difficult attainment.

Pathology of the Disease.—Mr Wilson has laboured hard to prove that the cell-structure in favus is not a vegetable growth, but merely an aberration from the normal development of the epidermoid cells. In this opinion I think that he is wrong. Vegetable and animal cells resemble each other so closely in their microscopical characters, that it is impossible for the acutest observers to discriminate between them. Professor Quekett says, in his Lectures on Histology: "However striking the difference between the animal and a plant may seem at first sight in the higher groups, a more extended examination shows that animals and plants gradually approach each other as we descend in the scale until they meet in a common centre—the simple or individual cell. At this point all means of distinction between the vegetable and animal organism end, and no feature exists which, in the present state of science, can enable even the most distinguished microscopist to determine to which of the two kingdoms the individual cell belongs, since it possesses characters common to both."

We can only, therefore, distinguish vegetable from animal cells by their respective modes of development. Now, in the present case, the cellular growths of favus are almost identical in arrangement with ordinary fungi. This is assumed by all observers, and allowed by Mr Wilson. On the ground of microscopic appearances, therefore, as well as of analogy, it is reasonable to conclude in favour of the vegetable nature of these growths. As Dr Hughes Bennett aptly says, "If long, hollow filaments, with partitions at intervals, containing molecules within their cells, springing from an unorganized granular mass, and giving off towards their extremities round, oval bodies or sporules, arranged in bead-like rows, be not vegetables, what are they?"

Mr Wilson's principal ground of argument consists of an assumption to the effect that the primary granule of the epidermoid cell is

formed in the cyto-blastema that exudes from the cutis in this disease, and that its complete form in the favus is an aberration of growth; that, in fact, the favus cell replaces the true epidermoid cell. Is this assumption correct? May not the exudation be so altered in properties and so deficient in vitality as not to generate these plastic granules at all? Or might not, again, the presence of the fungus altogether exhaust, by feeding upon it, the plastic powers of the blastema? Or, again, it is not improbable that some of the small granules contained in the crust are really granules proper to the exudation, but arrested in growth at that point; it being impossible, as I have already shown, to distinguish between vegetable and animal cells. In more complete proof, however, that the fungus of favus is identical with other forms of mould, Remak, as Dr Bennett relates, placed some favus crusts on the surface of a cut apple, which he then placed, with the cut surface downwards, on some moist sand, and covered the whole with a glass bell. On the sixth day a rapid growth of *penicilium glaucum*, with other kinds of mould, was discovered; but the Achorion Schœnleinii had disappeared. It would seem that the favus cells had been developed into the *penicilium glaucum*.

It has also been surmised by other writers, that perhaps the animal cells in this disease are really converted into vegetable cells: but this proposition involves a metamorphic principle of such great moment and universal application, that I deem it inexpedient to indulge in its consideration in connection with this limited subject. It admits, however, the proposition that there are vegetable growths.

On the whole, then, I see no reason to differ from those physicians and microscopists who regard these cell-growths as true parasitic fungi, developed from spores which have an external origin.

The favus plant, or the Achorion Schœnleinii, consists of small cells, of irregular size, but rather longer than broad, sometimes solitary, at other times joined together at their ends, and occasionally branched. It is composed of *spores*, which are the reproductive organs; the *receptacle*, which contains the spores; and the *mycelium*, or the plant itself. The plant is in fullest development near the surface of the crust.

There is much difference of opinion as to the site of these parasitic growths; whether it be the surface of the cutis, or the hair follicles. Whilst considering this part of the subject, I shall treat of Ringworm and Scall Head together. In the case of *Ringworm*, Gruby, who first noticed the cryptogame, traced it into the hair follicle, where a great number of them surrounded the cylinder like a sheath. Burgess agrees with Gruby. Wilson also considers the hair and the epidermoid lining of the follicles to be the seat of the disease. Beale and Jenner are of a similar opinion. Dr Neligan, however, considers it rather a disease of the scalp than of the hair; but his views are peculiar in considering the disease to be simply a herpetic eruption (in which opinion he is followed by Cazenave, whose knowledge of the disease was, however, limited, it being a rare affection in France): and, further, he does not make any reference to the existence of a parasitic fungus.

With respect to *scall head*, Wilson regards it as a disease of the hair follicle, giving a similar description to that of Gruby. Cazenave thinks that the true seat of the favous pustules is at the extremity of the piliferous duct. He does not, however, believe in a vegetable growth. Bennett has also found the fungus in the follicles, and encircling the hair. It is unnecessary to cite further opinions. It is not clear that the disease always originates in the hair follicles, though these become the seat of the cryptogame very soon after the disease is established. Hairs may be removed from a portion of the affected scalp which do not manifest any disease. Alike in the case of ringworm and of scall head, the scalp and the hair follicle are both affected.

(To be continued.)

THE SPIRIT OF THE PERIODICALS.

Dr Goodfellow continues in the 'Medical Times and Gazette' his Lectures on *Bright's Disease*. We extract his description of the different forms of kidney disease:

"I am fully sensible of the difficulty I impose on myself in attempting to give, in little more than one Lecture, an intelligible account of the several forms of Bright's kidney, which have been described by writers, and to which I have made allusion in previous Lectures. You are aware that since I have occupied the Chair of Medicine in this College, jointly with Dr Stewart, I have been in the habit of describing the several forms of diseased kidney included in the general denomination of Bright's disease, as modifications, or a more or less extensive commingling of two leading typical forms, commonly and very aptly termed the large white kidney, and the small, hard, contracted kidney. I say modifications, or a mixture of these two, but not gradations; for I believe, from an experience of some years, and somewhat close observation, that Dr Bright and his followers (especially Dr Wilks, whose very able and pains-taking investigations of these pathological conditions of the kidney entitle him to rank among the highest authorities on this subject) are quite right in their opinion, that these two forms are essentially different, and never pass by any pathological process from the one to the other. In entertaining this opinion, however, I do not ignore the fact that the process which leads to the one form may be engrafted upon the other, or that, from special causes, constitutions, and states of body, the two processes may go on contemporaneously, and so form a mixed kidney, that is to say, a kidney having a more or less close resemblance to both these forms, either in the same or in different parts. Now the essential characters, speaking roughly, of these two forms of kidney are the following:—

"1. *The Large White Kidney.*—It is, as its name implies, larger than the normal kidney, varying in size from six to twelve ounces, or even more; its external, cortical, or secreting part is increased at the expense of the internal, medullary, or purely excreting parts, measuring generally, between the base of the pyramids and the investing capsule, from half-an-inch to an inch or more; it is of a whitish or yellowish-white colour, flaccid, and anæmic, partly from the obliteration of the vessels, partly from the more or less abundant serosity, and partly from the diminution in the amount of blood-corpuscles. There may, however, be, and there often are, a few enlarged and turgid veins, which in the interior are tortuous, and on the surface have an arborescent form; the medullary portion may present various degrees of engorgement, or may be as exsanguine as the cortical portion, but this, so far as my experience goes, is rare. The course of this disease is generally rapid; it is always accompanied by considerable general dropsy; and the urine is generally scanty, smoky, and contains large quantities of albumen, some blood-casts of tubes, epithelial and exudative casts, and some red blood-corpuscles, and, at the later stages of the disease, more or less fatty matter. The duration is seldom longer than from four, five, or six to eight or twelve months: it may, however, persist even longer in some rare cases.

"2. *The Small, Contracted Kidney.*—It is invariably smaller than the normal kidney, sometimes only half the natural size; it is hard, contracted, red, and granular; the external or cortical part is wasted, and therefore much diminished, without any corresponding increase of the tubular portion.

"This form is chronic in its nature, its duration occupying many years, and is very seldom found without evidence of a similar process in other organs, especially in the liver, and not infrequently in the spleen and heart; and it is more than probable that these have been affected contemporaneously with the kidney, from the influence of some cause affecting the body generally.

"The symptoms of this form are somewhat obscure; certainly not so evident as those characteristic of the other and more acute form. They are more of a secondary character, and more particularly referrible to remote organs, rather than to the kidney itself from the effects of the disease, and the retention of the urinary constituents, upon the blood, and upon the nutrition of the body. The general tissues of the body suffer degradation, and the subjects of the disease are cut off from some other disease, as apoplexy or other head affections, pneumonia, pleurisy, pericarditis, peritonitis, &c., to which they have become predisposed, owing to the general dyscrasia produced by the insidious and unsuspected progress of the kidney affection; they die from pyæmia, erysipelas, or other causes, after accidents or surgical operations, which are not in themselves mortal, and not usually followed by a fatal result. The urine in this form is, as a rule, as abundant as in health, sometimes even more abundant; it is of low specific gravity; it may or may not contain albumen: generally the only effect of applying heat, and adding nitric acid, is to render the urine slightly opaline, but to produce no sediment or actual precipitate; it scarcely ever contains any casts of tubes, either epithelial or exudative. There is very seldom any anasarca. If there be any, it is small in amount, and then generally only at the close of life. But in many cases, on looking attentively, you may, as I have stated in a preceding Lecture, detect a slight œdema beneath the conjunctivæ, and in the feet at night, and a general puffy condition of the eyelids and of the loose subcutaneous tissues. The more positive or evident symptoms and signs of this form are pallor, neuralgia, headaches resembling those characteristic of hemicrania, noises in the ears, motes before the eyes, and other symptoms referrible to the nervous system—dyspeptic and other symptoms indicative of gastric and intestinal irritation, and even inflammation: for even extensive ulceration of the stomach is occasionally found with this condition of kidney; but whether it be an effect of it, experience has not enabled me to decide, although it is not improbable.

"Now, as I have said before, and indicated in preceding Lectures, every kind of modification of these two forms may be met with, but never any true gradation from the one into the others—that is, from the large white, or most acute form, into the hard, contracted, and more chronic disease. There may be, from some peculiarities in the nature of the cause, the habits of life, and constitution of the individual, a state partaking of both characters, or the one process may attack a kidney previously the seat of the other process, and so in a manner become engrafted upon it, in which case the organ will of course present the characters of both. It may or may not be larger than normal; generally it is. It is much less pale than the large white; its vessels are much more numerous, and more or less gorged with blood; the Malpighian tufts are red and solid, and the organ presents a coarse granular appearance. The symptoms, as you might be prepared to expect, are much less acute than in the large white form, and more decided than in the purely chronic form. The urine is very seldom free from albumen; it may contain a very considerable quantity; the specific gravity is considerably under the average, but never so constantly low as in the small, contracted kidney; there is almost always more or less deposit of albuminofibrinous casts of tubes both large and small, and also casts of imperfect, broken-down granular epithelium, in which there generally are some minute fatty molecules, and a few isolated blood-corpuscles. There is commonly considerable anasarca, with great proneness to effusions in the serous cavities, and even inflammatory formations—as flakes of lymph, &c.

"Besides these two leading, typical forms, and the third or mixed form, there are two others mentioned by writers, namely, the Waxy, Lardaceous, or Amyloid kidney, and the Fatty kidney. These may be modifications of the first form (the large white), or they may be produced by an independent morbid process. They much more rarely accompany the hard, contracted type of kidney.

"You will perceive that the terms lardaceous, waxy, and amyloid are synonymous, and are used

originally by Rokitansky, from the supposed resemblance of the kidney when so affected to to indicate the same disease. The first was used bacon rind. The second was a name given to it by some English pathologists from a fancied resemblance to wax, and the third is the term given to it by Virchow, because of its offering reactions on the application of iodine and sulphuric acid, resembling, if not identical with, those of the same agents upon starch.

"This form of kidney must be rare, for I have not met with it in my practice at this Hospital. But now that we have the means of detecting this degeneration even when partial, and before it has become so general as to affect the whole cortical substance, so as to be apparent to the naked eye, we shall doubtless find it more frequently; for I have for some time had the impression that this change or metamorphosis must be frequent in scrofulous and phthisical patients, and have often been surprised at not discovering palpable evidence of it in the dead-house. Virchow says 'that a large proportion of the cases of Bright's disease, especially the chronic ones, are assignable to this change' (into the lardaceous, waxy, or amyloid condition), 'and must, therefore, be separated from many other similar forms as constituting a special, altogether a peculiar affection." From the interesting account of this condition given by Dr Harris, it appears that the kidneys are generally enlarged, and that the cut surface of the cortex is of a pale yellowish-white colour, here and there irregularly depressed, the depressions giving the surface an uneven lobular appearance. The capsules strip off readily, leaving the surface smooth, and not torn. The symptoms of this form of kidney are obscure. There is generally anasarca more or less considerable, a great proportion of albumen in the urine, and also some small pale waxy casts, and a few epithelial cells, and red blood-corpuscles. The specific gravity of the urine is generally under 1012. It being a constitutional disease, and the urine containing but a very small proportion of urea, the general symptoms are severe, especially the nervous symptoms.

"The next form is the fatty kidney. In most, indeed in all, of the other forms of these affections, the kidney may undergo the fatty metamorphosis, but especially is it prone to take place in the large white kidney, and in the mixed white and granular kidney. Virchow has found that the kidney whose epithelium has passed into a fatty degeneration nearly always shrivels up, and the result is a permament atrophy. But when the pure typical white kidney undergoes this metamorphosis there is but little diminution in size, and the exudative matter deposited in the tubules and intertubular substance seems to undergo still further degeneration into fatty and oily matter. This condition will generally be found in persons who have been addicted to intemperance—especially in the use of undiluted spirits, as brandy, gin, and whisky.

"The symptoms indicative of the fatty kidney will more or less be modified according to the conditions of the organ with which this metamorphosis is associated, and also with the greater or smaller amount of this degeneration in other organs of the body, especially in the heart and arteries. There is generally very considerable anasarca, although great fatty degeneration of the organ has been found where no anascarca was observed during life. The same may be said, also, with regard to albumen. When the white kidney is the seat of the metamorphosis, you will invariably find considerable anasarca, and more or less of albumen, and of fat or oily casts in the urine."

The Author then describes the order in which these forms of disease are induced, and makes some observations on the processes of transudation and exudation.

Dr Conolly continues in the same journal his *Recollections of the Varieties of Insanity*. Mr T. Pridgin Teale, Jun., contributes a series of cases of *Iridectomy*. We quote a few, with the Author's remarks:

"As the subject of iridectomy is now under discussion, I have selected the following from among the cases in which I have performed the operation, as confirmatory of the results obtained by other surgeons:—

"Chronic Glaucoma.

"Mary T., aged 50.

"*Right eye.*—Blind from chronic glaucoma.

"*Left eye.*—Failing one year; she can read large print; globe hard.

"January, 1859.—Iridectomy of left eye.

"October, 1860.—Vision, which had progressively failed for a year, has remained stationary since the operation. She can read No. 6 Jaëger with the aid of convex glasses. Globe less hard than before the operation, though not quite of natural tension.

"In this case the disease, which had progressed in the right eye to complete blindness, was arrested in the left at the stage at which the operation was performed.

"Sub-acute Glaucoma.

"Mrs S., aged fifty-four, for ten months has suffered from intense unremitting pain in the brow and left side of the head.

"*Left eye.*—Perfectly dark many months; cornea hazy; aqueous humour turbid; conjunctiva dusky red colour; globe hard.

"*Right eye.*—Globe hard; cornea and aqueous humour clear; lens opalescent; states that she has occasionally perceived the light of a candle during the last two or three months, but that generally she has no perception of light.

"December, 1859.—Iridectomy of both eyes. The day following the operation, the neuralgia was less than it had been for many months.

"October, 1860.—During the three weeks following the operation, the pain gradually abated, and has never returned. Globes of natural tension. She has regained a small amount of sight with the right eye, being able, early in the morning, to see the window-frames, and to distinguish fingers. The relief of pain and arrest of the glaucomatous process were perfect. The recovery of the small amount of sight was quite unlooked for at such an advanced period of the disease."

"Iritis with closed Pupil.

"Joseph B., aged twenty-nine. For a year has suffered from repeated attacks of syphilitic iritis, which during the last six months have been attended with constant severe pain. He has been for some time perfectly blind. In the right eye there is total synechia posterior, the iris bulging forwards, and the cornea being ulcerated. The left eye was destroyed by a blow many years ago.

"September 4, 1858.—As no treatment had of late mitigated his sufferings, iridectomy was performed, without, however, any expectation of recovery of sight.

"12th.—He is free from pain. Ulcer of cornea healing.

"October 2.—The patient having slept in a draught, the eye again become inflamed and painful. Iridectomy was therefore repeated.

"January, 1859.—Has been perfectly free from pain for many weeks. The ulcer of the cornea is healed, and the globe is in a quiescent state.

"In this case, although there was no hope of sight, the object of the operation was attained, namely, relief of pain, and arrest of constant irritation of the globe; results which ordinary means of treatment, continued for several months, had failed to obtain.

"Iritis with 'Exclusion' of the Pupil.

"Sarah F., aged forty-nine. Iritis of left eye nine months. Constant and often intense pain six months, during which she has been under medical treatment (apparently mercurial, as her gums were made tender) without any relief. Total synechia posterior. She can hardly count fingers in a strong light. Right eye blind since infancy.

"May 14, 1859.—Iridectomy of left eye.

"17th.—Slight increase of iritis, with diminution of pain.

"June 3.—Eye free from pain and redness. A few weeks later she could read large letters equal to 19 Jaëger, and could walk by herself through the streets.

"October, 1860.—She has had no return of pain nor inflammation since the operation."

"Interstitial Corneitis.

"Maria C., aged twenty-eight, unmarried, suffered from inflammation of the eyes for the first time three months ago, after being harassed for several months by attendance on an invalid. There is no reason to suspect primary syphilis. Her teeth are dwarfed, transversely grooved, and wide apart, such as Hutchinson describes as the result of hereditary syphilis. Before she was born, her mother had had seven miscarriages and dead children in succession.

"*Right eye* inflamed three months; cornea mottled and universally opaque, so that the iris could not be seen; globe very soft; vision reduced to bare perception of light.

"*Left eye.*—Cornea mottled with red and white interstitial patches, with one or two clearer portions at the margin through which the iris can be distinguished. Can see the light of a candle, but cannot count fingers; globe soft.

"July 25.—Iridectomy of both eyes, with the double object of at once arresting the inflammatory processes which had already advanced to such a damaging extent, and also with a view to providing an artificial pupil opposite to the remnant of transparent cornea in the better eye.

"26th.—Pain and intolerance of light much relieved. Has slept better than she has done for several weeks.

"August 6.—Slow but steady improvement since the operation.

"10th.—Alterative treatment commenced.

"September 1.—Alteratives discontinued. The improvement in the condition of the eyes seemed to be rather more rapid under their influence.

"October 30.—*Right eye.*—Globe has recovered its natural tension, and is free from irritation. Mottled opacities throughout the entire cornea. Can count fingers at four inches distance.

"*Left eye.*—Tension almost natural. Slight tenderness and redness round the cornea. Counts fingers at seven inches.

"From the foregoing cases, and others in which I have performed iridectomy, I am firmly convinced that we possess in this operation a most powerful agent in arresting many disorganising processes in the eyeball which were little, if at all, under the control of any method of treatment previously in use. In many of the cases a greater or less amount of vision has been restored. In others, where recovery of sight was impossible on account of permanent change of structure in the retina or cornea, dependent on the length of time during which the disease had remained unchecked, there has still been obtained incalculable benefit by relief of pain, and arrest of disorganising processes. Of these latter cases I believe there is hardly one in which sight would not have been preserved or recovered, if the operation could have been performed at an early period of the disease."

A *Case of Ovariotomy* is reported in the same journal by Mr Spencer Wells. We will reproduce it next week.

The 'Lancet' opens with a continuation of Dr Pavy's Lettsomian Lectures on *Diabetes*. We extract the following paragraphs:

"Such are the sources of sugar that were known previous to Bernard's time. Now, after an attentive examination of the circumstances connected with Diabetes, Bernard was led to think that there might be something besides amylaceous matter—something unknown to chemists and physiologists, which might give rise to the production of sugar in the body. This he particularly inferred from the fact that the quantity of sugar escaping from a diabetic patient, under a mixed diet, is much greater than can be accounted for by the starch and sugar ingested; and that, although saccharine and amylaceous materials may be completely abstained from, still sugar does not cease to appear in the urine. Here was his motive for undertaking an experimental investigation, out of which have sprung such unanticipated results. In his first experiments, animals were kept upon a diet of a strongly saccharine character, with the view of ascertaining how far the sugar could be followed in the circulatory system after its absorption into the branches of the portal vein. His results led him to the conclusion that it might be detected as far as between the liver and the right side of the heart. To show that the sugar encountered at this point was what was derived from the food, a counter-experiment—an experiment where starch and sugar were excluded from the diet—was made, with the expectation of obtaining a negative result. Instead of this, however, to Bernard's great astonishment, sugar was found as before; and thus was laid the foundation of the theory which has given to the liver

a gluco-genic function. It was in the year 1848 that the discovery of this function was announced.

"Bernard's celebrated experiment, which was regarded as establishing the existence of a sugar-forming function in the animal system, was this:—A dog was kept for some time on a purely animal diet, and was, therefore, prevented from receiving any sugar from an external source. Its life being suddenly destroyed, the abdomen was immediately opened, and a ligature placed on the portal vein. The blood flowing from the chylopoietic viscera towards the liver was obstructed, and distended the vein below the ligature. An incision into the distended vessel allowed the blood to escape, and this, on being collected and tested, gave no indication of the presence of sugar. Blood was now procured from the hepatic veins on the other side of the liver, and was found to be highly impregnated with saccharine matter. The liver tissue itself was examined, and gave a strong reaction, whilst all the other solid organs of the body and the contents of the stomach and intestine gave no reaction with the sugar tests.

"Nothing, certainly, seems more conclusive than such an experiment as this. There is no sugar in the blood going to the liver, and there is an abundance in that escaping from it, as there is also in the tissue of the organ itself. Such evidence really appears in unmistakeable langnage to indicate that sugar is formed by the liver, and carried away from it by the hepatic blood. And, from the extent to which the sugar is found, it might be reasonably inferred that its production is connected with some very important purpose in the animal economy. Now, the experiment establishes beyond all question that sugar can be produced in the animal system without being derived directly from the food; but the great point of interest in physiology, and likewise as regards the pathology of diabetes, is whether this production is really taking place during life, in accordance with the inference that has been drawn from Bernard's results obtained after death. Does, in fact, the examination, as it has been hitherto conducted, afford us an indication of the physiological state? or can it be only taken for what it is really worth—namely, as the representation of a post-mortem condition? This I shall specially touch upon when I have proceeded a little further, and brought the history of the subject up to the present period.

"It was at first considered that the sugar found in the system of the animal feeder was formed from an albuminous material. Bernard's next step—and an important one it has proved—was to discover and isolate the substance which is the source of animal glucose. In September, 1855, he communicated to the Academy of Sciences of Paris his discovery that the formation of sugar in the liver might be shown to be capable of taking place after death. On passing a stream of water through the vessels of the liver after removal, the whole of whatever sugar impregnated its tissue was washed out, so that it then gave no reaction with the copper or fermentation tests. Upon placing it aside, however, and examining it again some time afterwards, a strong indication of the presence of sugar was to be obtained. All question of a special vital process was by this experiment removed, and the production of sugar resolved itself into a simple chemical action. The source of the sugar was not as yet disclosed; but it was evident that in the liver it must be, and that it must consist of something not so easily taken up by water, otherwise it would have escaped from the organ with the sugar. In 1857 the isolation of the sugar-forming material was announced, and as sugar-formation was supposed to constitute its physiological destination, it was called by Bernard the Gluco-genic Matter of the liver. The gluco-genic theory was considered to remain unaltered by this discovery, except in so far as it was rendered more complete by the detection of a recognisable source for the animal glucose.

"My researches have led me to look upon the term gluco-genic as objectionable, if applied to this newly-discovered substance upon physiological grounds. It is true that, after death, under certain unnatural conditions, it is a sugar-forming substance; but under natural circumstances it does not seem intended for the production of sugar. On account of its chemical resemblance to a product of the vegetable kingdom, it has also been called the Amyloid Substance. To this term, however, an objection might be raised on the score of confusing this substance with a body of a different nature met with in the system that has long since received the same name. In speaking of it myself, I have called it Hepatine, simply from its connection with the liver. When our knowledge of its physiological relations is more perfect, it can then be named upon scientific principles; but until then its provisional name should certainly be one which is not exposed to the chance of leading to error by implying a purpose I have good reason to believe it is not naturally intended for.

"The situation of hepatine in the liver is in the hepatic cells—at least, such is to be inferred from what is seen by the use of the microscope, with the employment of chemicals. As it is not present after death from disease, but is always present under healthy circumstances, its production may be supposed to result from the exercise of the normal functional activity of the liver.

"In its chemical properties hepatine is allied to starch, but even more closely so to dextrine. When pure, it is a neutral, colourless, tasteless, and inodorous body, presenting only an amorphous granular appearance under examination with the microscope. It is largely soluble, although not with rapidity, in water; and its aqueous solution presents an opaquely lactescent character. It is curious that in the form of a highly concentrated solution it is transparent, the lactescence appearing only on dilution. It is insoluble in alcohol and glacial acetic acid, by which agents it may be thrown down from its aqueous solution. It is unaffected at a boiling heat by caustic potash. It is devoid of nitrogen, and is composed of C_{12} H_{12} O_{12}. With iodine its behaviour is like dextrine, producing a deep wine-red coloration. Its most important property is its susceptibility of transformation into sugar. It does not itself react with the cupro-potassic or fermentation tests; but, after boiling for a short time with a mineral acid, or contact with many animal products, as saliva, blood, liver tissue, &c., at a moderately elevated temperature, the characteristic indications of glucose are discernible. For studying its relations, it is easily procured by plunging a piece of liver removed from a recently-killed animal into boiling water; then pounding in a mortar, and boiling afresh with a fairish quantity of water. The strained or filtered liquid is to be poured into five or six times its bulk of spirit to precipitate the hepatine, which, after being collected on a filter, is to be dried. To obtain it pure, it must be boiled in a solution of potash. After reprecipitation with spirit, it is to be thoroughly washed with that agent to effect the removal of foreign matter. But traces of the alkali cling to it with great tenacity, and these can only be got rid of by neutralizing with an acid, such as the acetic. The acetate formed is carried away by the spirit in washing."

The same journal contains a continuation of Mr Henry Thompson's Annual Oration, and a controversial article by Mr Hulke on the *Surgical Treatment of Glaucoma*, in which the Author seeks to overthrow Mr Hancock's arguments against iridectomy. Mr Baker Brown continues his reports of cases of *Vesico-Vaginal Fistula*. We extract them:

"Case 8.—*Vesico-Vaginal Fistula; obliterated urethra of eight years' duration; one operation; cure.*—Mrs B——, aged forty-two. This lady was sent to me by Mr Ludlow, of Hinckley, Leicestershire; but that gentleman did not attend her in her confinement.

"*History.*—Eight years ago she was taken in labour with her first child, and after twenty-four hours of severe pains she became insensible. She believes that instruments were applied, but is unconscious of their nature; by their aid she was delivered of a still-born female child. She had fits for some time after the labour, and when she became conscious she found that her urine came away involuntarily, and it has continued to do so ever since. She has never menstruated since the accident.

"Aug. 11th, 1860.—On examination, I found a fistulous opening which would admit three fingers, situated about two inches up the vagina. The urethra was entirely occluded. There was a slight corrugation at the point where the meatus should have been. The vagina was large and roomy.

"13th.—Chloroform having been administered by Mr Wratislaw, I proceeded to operate in the presence of Messrs George Brown, Philip Harper, Spencer, and my son, Mr I. Baker Brown. I first freely pared the edges of the fistula, which were very hard and cartilaginous, and passed through them five silver sutures. Having done this, I introduced a long sharp-pointed knife into the centre of the corrugated part which pointed out the situation of the meatus, and gently pushed it into the bladder, keeping as nearly as possible in the track of the urethra. Through the opening thus made, which was nearly two inches deep, a metallic catheter with bag attached was passed. The sutures were then closed, one being simply twisted, but the other four were secured by my bar clamps. In the evening the catheter became closed up with coagula, and it was found necessary to withdraw and cleanse it.

"From this time she went on very well, having no escape.

"On the 20th the bar clamps were removed, and the whole opening was found perfectly healed. The catheter was retained in the bladder for a few days, after which, as the new urethra was found covered with mucous lining, it was withdrawn, and she was ordered to have her urine drawn off every four hours. In a month from the operation, she could pass a certain quantity of her urine herself; but as the bladder had not entirely recovered its powers of contractility, she could not quite empty it. She was, therefore, directed to pass the catheter about three times a day. None of the urine escaped involuntarily.

"*Remarks.*—Nothing could be more satisfactory than the success which attended the treatment of this very unusual condition, considering the length of time which had elapsed since the accident, and the total occlusion of the urethra. I have since heard from her. She menstruates regularly, and never loses any urine. She is still obliged to pass the catheter occasionally; but I doubt not that when the bladder has recovered its contractile power she will gradually be able to empty it without the use of the instrument.

"Case 9.—*Vesico-Vaginal Fistula, with complete Ruptured Perinæum; three operations for the fistula; cure.*—This and the two following cases are taken from reports of the London Surgical Home:—E. B——, aged forty-one, married, living at Leicester; has had thirteen children; admitted July 20th, 1860.

"*History.*—On the 1st of April, parturition commenced; was in labour fifty-two hours, when craniotomy was performed. She was very ill afterwards, losing the use of her limbs. The urine escaped per vaginam immediately after the labour, and she has never passed any since by the natural passage. Diarrhœa also came on after labour, and ever since then the motions have passed away entirely without control. Early in June she went to the Leicester Infirmary, under the care of Mr Paget, who, in consultation with his colleagues,—Messrs Macaulay and Benfield,—recommended her to place herself under the care of Mr Baker Brown.

"On examination, the posterior part of the vagina was found contracted by bands of cicatrization, immediately behind which could be seen a small portion of the os uteri. Directly anterior to these adhesions was a long fistulous opening, running up into the left side of the vagina and bladder, in extent altogether about two inches. The whole of the perinæum was gone, and the anterior half of the sphincter muscle also.

"Aug. 2nd.—Mr Brown operated for the fistulous opening, the patient being under the influence of chloroform, and placed in the lithotomy position. Seven bar clamps were used, and put horizontally along the wound. There having been no escape of urine, on the 10th the clamps were removed, and the union seemed perfect; but, on the following day, Mr Brown found that about half of the opening had again separated. She was, therefore, placed under tonic treatment, with a view of improving her general health.

"16th.—Mr Brown operated a second time, the patient being placed on her hands and knees, and not under the effects of chloroform. He used a button and five shots, and brought the edges together transversely.

"25th.—The button was removed, and all was found healed, except a small portion where one wire had torn through.

"Sept. 13.—Having regained her health, Mr Brown operated again, the patient being on her hands and knees. Bozeman's button was used.

"22nd.—The button having been removed, it was found that the most perfect union had taken place.

"*Remarks.*—The reason, in the first instance, of a partial failure in the union arose from two causes: first, from the cicatrised band, which pulled upon the edges; and, secondly, from the low condition of the general health of the patient. It would have been better to have divided those adhesions, and to have waited two or three weeks before operating. In a similar case, such would be my practice. I may just mention, that the usual operation for ruptured perinæum has since been performed with perfect success, and the patient is now entirely relieved from her miserable condition.

"CASE 10.—*Vesico-Vaginal Fistula, very large size; four operations; cure.*—S. H——, aged twenty-eight, married, living at Chichester; admitted into the London Surgical Home, April 5th, 1860.

"*History.*—She has had one child, eight weeks ago, in labour thirty hours, when craniotomy was performed; suffered from retention of urine for the first four days, when the catheter was employed. From that time no urine could be retained. This history was obtained from Mr Buckle, who was called to see her after this condition was ascertained.

"On examination, Mr Brown found strong bands of adhesion almost closing up the vagina, and with an opening about the size of a five-shilling piece, which not only embraced the whole floor of the bladder from the termination of the urethra to the os uteri, but extended also to the left side of the vagina, destroying much of the tissues thereof. Mr Brown freely divided all the bands of cicatrization, and afterwards dressed them with oiled lint, and then for many days used the usual sponge tents.

"March 22nd.—Mr Brown did not consider it advisable to attempt to close the whole opening; he, therefore, operated on a portion of it with three bar clamps.

"29th.—Removed the clamps, and the part operated on was found quite healed.

"April 5th.—Several strong bands of cicatrization, still dragging upon the edges of the fistula, especially on the left side, were again divided and dressed as before.

"May 31st.—The fistula being now the size of half-a-crown, Mr Brown brought the edges together with seven bar clamps.

"June 7th.—Bar clamps removed; only a small portion had soundly healed, evidently because the patient was weak and out of health. She was, therefore, put under tonics and out-door exercise.

"July 26th.—Mr Brown operated, using six bar clamps.

"Aug. 4th.—Clamps were removed. A large portion was found healed; but in consequence of the very bad state of health of the patient, it seemed impossible to close the whole. She was, therefore, sent to Brighton for a month.

"Sept. 13th.—She returned much better in health, but some strong bands still constricting the vagina on the left side. Mr Brown freely divided them.

"Oct. 18th.—Mr Brown again operated, using Bozeman's button and seven shots.

"27th.—Button removed. Complete union had taken place.

"*Remarks.*—This was one of those cases offering great difficulties, not only on account of the very large fistulous opening, but also because of the general bad health of the patient from the time of her admission, materially aggravated by a great fretfulness of disposition. It was one of those cases which no young surgeon, however clever, could have succeeded in curing by one operation

"CASE 11.—*Vesico-Vaginal Fistula, with a large Recto-Vaginal Fistula; one operation; cure.*—J. M——, aged twenty-one, first child; admitted into the London Surgical Home on the 30th of July, 1860.

"*History.*—Was taken in labour on the 24th of April, and delivered on the 25th by craniotomy, having been in labour thirty-five hours. Ever since that time the urine has escaped per vaginam. Was sent up from the Leicester Infirmary by Mr. Paget.

"On examination, a fistula was found situated immediately behind the symphysis pubis, transversely, destroying half the urethra; the whole so tightly bound down by cicatrized bands, that it was almost impossible to pass a catheter from the meatus into the bladder.

"On further examination, it was found that all the recto-vaginal septum, extending two inches up, and including the whole of the base of the perinæum, had sloughed away, only a very superficial perinæum, composed merely of skin, remaining. This, therefore, was cut through, and the parts dressed with oiled lint. From this time, the whole vagina put on a most unhealthy, sloughy appearance, and for many weeks seemed to baffle every treatment, until Oct. 18th, when she regained her health sufficiently to admit of the division of a band which constricted the vagina, which quickly healed; and on Oct. 25th, Mr Brown operated, the patient being in the lithotomy position, under chloroform, Bozeman's button and six silver wires being used. At the same time, Mr Brown closed the recto-vaginal fistula, up to the anus, using a button and three wires.

"Nov. 3rd.—Buttons taken off. The vesico-vaginal fistula was found quite healed, but the rectum was not healed, the edges looking unhealthy.

"*Remarks.*—This case is one of great practical interest, from the fact of the patient being in such a bad state of health as to delay the first operation for three months. The propriety of the delay is proved by the rapidity of the union at the first operation.

"If these eleven cases be added to the twenty-nine which I have already published, it will be seen that they amount to the number of forty. Of these, thirty-eight were cured as far as the fistula was concerned, although one subsequently died of pyæmia."

Dr HASSALL contributes a paper to the same journal on the danger of *Green Paint in Artificial Leaves and Flowers;* a danger arising from the use of Scheele's green, or arsenite of copper, as a colouring material. We extract the following:

"The use of emerald green for the manufacture of artificial leaves and flowers has been for the most part resorted to only within the last two or three years, and I am informed that there are from two to three hundred leaf-makers, all using this poisonous substance. The condition of these people, mostly young women and girls, but including some men and boys, is wretched in the extreme. They all labour, and many in a severe form, under symptoms of arsenical poisoning. The poison is diffused throughout the atmosphere they breathe, and is of course inhaled; further, it acts as a local irritant and escharotic on the hands and other parts of the body to which it becomes mechanically applied. The symptoms may be arranged into the constitutional and local: the former consist of general derangement of the health, debility, nervousness, headache, thirst, sickness, loss of appetite, and diarrhœa; the latter, in soreness of the throat and gums, œdema about the eyes, soreness of and running from the nose, and in ugly-looking sores on the hands, face, neck, and other parts of the body to which the poison finds access.

"Now, for all these evil effects, no necessity whatever exists. In the first place, it is more than probable that a suitable substitute for the arsenical pigment might be found; and in the second, even if its use could not be dispensed with, it is certain that the more injurious and distressing consequences might be avoided by the adoption of certain simple and obvious precautions.

"Hitherto reference has been made only to the effects of the employment of the pigment on those engaged in the manufacture of the leaves and flowers. Is is highly probable, however, that the wearers of these ornaments do not altogether escape from the serious consequences to which their poorer sisters are subject.

"*Case* 1.—Francis H——, aged forty-five, was admitted an out-patient of the Royal Free Hospital, in February last; is a dyer of muslin sheets used for making the leaves and other parts of artificial flowers; has been engaged at this occupation off and on for about two years; used formerly to dust the colour—arsenite of copper, or emerald green—on the muslin. This occasioned it to fly about the room, and to fall on the clothes: began almost immediately to feel ill; suffered constant nausea, loss of appetite, thirst, and headache; had diarrhœa occasionally, soreness of the throat, and tenderness of the gums; is much more nervous than formerly. The eruption appeared four or five days after commencing to use the pigment. It began in the form of greenish pimples over the hands and face; these bursting, left holes, having eroded edges. Has also eruptions on the scrotum and groins. The skin of the palms of the hands is of a yellowish-green colour, being stained with the green dye. Left off using the emerald green at Christmas, 1858, for about four months; then used picric dye, which did not affect him, and, in two or three months, the eruptions entirely disappeared. Began to use the emerald green again about six weeks before Christmas, 1859, and soon experienced nearly the same effects as before, with this difference, that the eruption was not so bad, owing to the manner in which the colouring matter is now applied, not by dusting as formerly, but by dyeing the muslin and rubbing in the colour.

"CASE 2.—Richard G——, aged twenty-seven, also admitted an out-patient of the Royal Free Hospital, in February last; is an artificial leaf-maker—that is, he cuts the leaves out of the dyed sheets of muslin; has been engaged in the trade about twelve months; was in good health until he began to use the emerald green about two or three months since; began to feel the effects of the poison in the course of two or three days afterwards. The symptoms were as follows: Much thirst; tongue white; highly nervous; sleep disturbed and unrefreshing; weakness; loss of appetite; bowels very much relaxed for the last eight or ten days, acting some six times daily; sense of weight on the chest and difficulty of breathing; the eyes swollen in the morning; the nose sore inside and discharging freely; gums tender. About fourteen days after using the colour, sores broke out in various parts of the body; on the hands, forehead, behind the ears, at the roots of the nails, and on the scrotum, the sores presenting a dark and very unhealthy appearance. The hands, especially the palms, and the roots of the nails, were stained, as in the previous case, of a greenish-yellow colour.

"There were eight young women and two boys working in the same room with the men whose cases have just been described, and they were all affected much in the same way. They all had sores; the girls, at the back of the neck, on the sides of the nose, and on the hands: their eyes were also affected, and there was running from the nose. To such an extent was their health affected, that they were compelled from time to time to give up their work and return home.

"P.S.—Arsenite of copper is employed for a great variety of purposes besides as a dye for colouring paper-hangings. In a letter inserted in the 'Lancet' some months since, I pointed out that it was constantly used in the colouring of articles of furniture and dress. I also showed that another green pigment, probably scarcely less injurious than the arsenical preparation, was still more constantly employed to colour carpets, table-covers, curtains, clothes, dresses, and numerous other articles. This pigment is known as false Brunswick green, of which three shades are prepared, and it consists of Prussian blue or indigo with CHROMATE OF LEAD."

The same journal contains a report, by Dr J. B. METCALFE, of a *Case of Poisoning by Arsenical Paper-hangings.* We extract the case:

"Clarence W. King, son of W. T. King, Esq., of Beresford Lodge, Highbury, aged three years and a half, first manifested symptoms of being unwell on the morning of Thursday, Nov. 1st. He refused his breakfast, complained of chilliness, and was sick; at ten a.m. he was seized with convulsions, for which he was put into a warm bath, and the attack soon passed off. On my arrival at eleven a.m. he was in a semi-comatose state, his countenance placid, surface of body warm; the bowels had acted several times, the stools passing off involuntarily, watery, bilious, and very offensive; pulse quick; tongue white; there was no abdominal tenderness on pressure. On visiting him

again in the evening, I learned that slight convulsive twitchings of the facial muscles had been observed; that he had been more feverish, but was again less so; he had not been sick; the bowels were less freely relieved.

"Thus far there were no symptoms of so grave a character as to lead to the supposition that they were attributable to any extraordinary cause; worms (to which the child was subject), or any other irritant, might have produced them. It was on the following day, at seven a.m., when having been sent for on account of another child having been seized with convulsions accompanied by violent shrieks and severe dysenteric discharge from the bowels, that I noticed the great change which had taken place in the little fellow; he was almost in a state of asphyxia, the surface cold, pulse feeble, countenance livid. The application of warmth, administration of ammonia, and frequent supplies of warm milk, after the lapse of a little time produced somewhat of reaction; but in the afternoon he was again seized with a severe tetanic convulsion, and from that time alternations of repose and convulsion (amounting to perfect opisthotonos) continued until the little sufferer sank at twelve o'clock, thirty-eight hours after the commencement of the attack.

"It is worthy of note that although all these symptoms were due to arsenical poisoning, as will appear in the sequel, there was no violent sickness; only once at the commencement of the attack was the child sick, and on one occasion on the second day when beef-tea was given instead of milk.

"A post-mortem examination was made on the following day, with reference to which it may be briefly remarked that the appearances were indicative of a healthy state of system; the child was fat and well nourished. For the appearances presented in the stomach and those parts which were forwarded to Dr Letheby, the reader is referred to the report which is appended."

Dr Letheby's examination proved that there were traces both of arsenic and copper in the liver. He remarks:

"The results of these investigations leave no doubt in my mind as to the cause of the child's death. The poisonous pigment existing in so large a quantity on the paper, together with the circumstance that the slightest friction would remove it, accounts fully for the origin of the poison; and the presence of it in the dead body answers the question as to the cause of death.

"It may not be out of place to remark that the quantity of the poison on the paper is sufficient, under circumstances like the present, to be a source of serious danger: for a piece of the paper six inches square contains enough arsenic to destroy two adult persons; and, from the many cases of a like character which have been referred to me, I cannot hesitate to believe that the use of such papers is extremely hazardous. Within the last fortnight, I have had occasion to examine two specimens of green papers which were suspected to be the cause of illness, and in each of them arsenic was present to a large extent; in one case it amounted to nearly ten grains on a surface six inches square; and it almost invariably happens that the poisonous pigment is but loosely attached to the paper, and is easily brushed off by slight friction. When our artificers and manufacturers will learn caution in respect of the use of such poisonous pigments I know not, for already the danger of it has been sufficiently discussed. Nor is there the excuse that, in order to meet the demand for bright and permanent colours, there is any necessity for the employment of mineral pigments. The French, who are our competitors in this matter, have long since abandoned the use of such pigments, and are yet able to outstrip us in the brilliancy of tint. It is high time that our manufacturers should imitate their example."

We quote from the 'Lancet' of the 24th ult. the following *General and Clinical Remarks on Scurvy*, by Dr Stephen H. Ward:

"The face of an individual suffering from advanced scurvy speaks distinctly of damaged as well as deficient blood. It is of a sallow, dingy, earthy hue, and looks also at times as if it were dirty; the conjunctivæ are clear and transparent, the eye usually bright, with dilated pupil, and the lips are bloodless. The countenance is generally passive and devoid of expression, though in some severe cases it expresses a sense of dread. Sometimes projection of one or both cheeks indicates the enlarged condition of the gums beneath. A peculiar fœtid emanation, something like that of putrefaction, but distinctive, is the next, if not the first and most striking, characteristic of the worst forms of scurvy. It comes out with the breath, and does not result from, though it may be aggravated by, a sloughy state of the gums. Scorbutic patients are generally found lying on their backs, with heads rather depressed, the position in which the weakened heart can best do its work. Frequently the bed-clothes are seen to be elevated by the raised contracted knees. On looking into the mouth, the gums are found, in a large proportion of cases, to be more or less involved, from a slightly projecting, spongy state, affecting the free margins, to an extensively hypertrophied mass, completely projecting over and between the teeth, extremely tender to the touch, and inclined to bleed. The colour of the gums, which varies from a deep red to a livid blue or black, abruptly terminates with them, and forms a striking contrast to the pale, anæmic appearance of the lips, tongue, and inside of the cheeks. At times there is ulceration and even sloughing of the gums, and consequent loosening of the teeth. I have found the tongue to present usually a clean and very smooth surface.

"On removing the bed-clothes, and examining the surface of a scorbutic patient, we find evidences of the damaged condition of blood in the exudation of its constituents—the blood-discs, the fibrin, and, more rarely, the serum. The extravasation of the coloured corpuscles occurs either in the form of small, hæmorrhagic, purpuric spots, or larger bruise-like stains. The hæmorrhagic spots vary in size from that of a mere point to that of a small pea, and in colour from a vivid claret, in the more sthenic, to a faint reddish-brown in the severer and more advanced cases. The large bruise-like stains, like the small petechial spots, are usually to be found on the lower extremities, and vary in size from a crown-piece, or less, to a stain involving the whole length of one of the legs from the upper part of the thigh downwards. It seems probable to me, from the fact that they affect, by preference, the inner surface of the limb, that they are produced by slight blows or by pressure, such as that caused by the weight of one leg resting on the other. They generally appear first, and are most marked, around the cicatrices of old ulcers or wounds.

"Not less distinctive of scurvy than the affection of gums and subcutaneous hæmorrhages, are the effusions of fibrin which take place in different parts of the body. Like the hæmorrhages, however, they usually select the lower extremities. The fibrin is either poured out beneath the skin, or between the tendons and bones which enter into the formation of the knee and ankle joints, and fixes them as in a splint. Effused around the knee, and into the popliteal space, it produces the characteristic contraction of this joint, which is often the earliest and sole evidence of the scorbutic taint. Effused beneath the skin, and forming a sheath around the muscles, it makes the fleshy portion of the leg or thigh indurated, and imparts to it a resistance like that of board. Effused upon the surface of the tibia, or the subcutaneous surfaces of other bones, beneath the periosteum, it gives rise to node-like swellings, which are often extremely tender, and simulate those of syphilis, save in the fact that there is no exacerbation of pain at night. The skin is firmly adherent to the effused fibrin, and cannot be pinched up: it is also generally of a brownish hue. There is usually much pain and tenderness connected with these effusions.

"The analysis of 100 cases of scurvy, recorded by me or by the resident medical officers, in order to determine the relative frequency of the more prominent symptoms, gives the following results:—In 74 out of the 100, the gums presented the different degrees of affection already noticed. In 34 cases there were the small hæmorrhagic spots: these were generally limited to the legs, sometimes to one; they at times extended to the thighs, and in several cases were scattered more or less over the body. In 36 instances, the larger ecchymoses were present. They varied in colour as do bruises in their different stages, and in sight as the smaller hæmorrhagic spots. In 58 cases there was more or less effusion of fibrin; the knees were the most constant seat of this effusion—then the hams, the calves of the legs, the ankles, the dorsa of the feet, the back of the thighs. Occasionally there were syphilitic-like nodes on the tibia, and, in one case, on the clavicle. In one instance there was much effusion about the biceps, in another about the elbow, preventing flexion of this joint; and in five cases, the back of the hand was swollen up into a hard, resisting, conical tumour. In three cases there was effusion of serum only in the legs, coupled with other scorbutic appearances.

"Further evidences than those already afforded of the damaged condition of the blood were given in the occurrence in several cases of passive hæmorrhages. These came from the nose, the mouth, or the bowels; never from the lungs, stomach, or bladder.

"The tendency to fatal syncope is one of the most striking features of scurvy, and is not limited to the more serious cases. Scorbutic patients, not particularly reduced in strength or emaciated, will, on any sudden over-exertion, especially on suddenly assuming the erect posture, sometimes fall down in a swoon, from which they do not recover. This fact is one of the most important to be borne in mind in the treatment of this disease. One of three fatal cases, which have occurred during my official connection with the 'Dreadnought,' was that of a man in the prime of life, and who appeared to be in very fair condition as regards flesh and power. He had been chatting in a loud and cheerful tone of voice to those near him, on the evening after his arrival, when suddenly, while the nurse's back was turned, on getting out of bed to go to the night-stool, he fell down in a state of syncope, and before the medical officer could get to him, was dead.

"What is the constitution of scorbutic blood? The general anæmia, the pale colour of the muscles and viscera, the free effusions of fibrin, tell us, what chemical analysis confirms, that it is deficient in red corpuscles, and superabounds in fibrin. The former have been found, in one instance, to be reduced to 48 parts in 1000, and the latter to be increased to three times its normal quantity. A careful microscopical examination of several specimens has been made by Mr Cooke, the resident medical officer, and also by myself, and the abnormal appearances were a general diminution of quantity of red corpuscles, a shrivelled or ellipsoidal appearance of some of them, an irregularity in the size, and, in one or two instances, a not very marked increase in the number of white corpuscles; and, in one case, some irregular-shaped granules were seen floating about in the liquor sanguinis.

"I have not space for many remarks on the general symptoms of scurvy. The state of tongue has already been noticed; the appetite has been usually found to be good; the alvine evacuations have generally been healthy, though in some cases diarrhœa has existed. The urine has been examined in regard to specific gravity, alkalinity or acidity, freedom from albumen, &c., but has not been found to present any material deviation from the urine of health.

"In the severe cases there is almost always sleeplessness at night, but not any disturbance of the intellectual functions. The pulse also, in bad cases, is very rapid, as high as 130, or 140 even; and there is heat of skin, and some febrile excitement, with free perspirations at night—a constitutional condition approaching that of hectic. Where these symptoms are present, there is always, as far as my experience goes, fibrinous effusion. I have not noticed, even in the milder cases, the dry, harsh skin which has been described as characteristic. The amount of emaciation is not always great, even in extreme cases."

CHLOROFORM PAREGORIC OF Dr HENRY HARTSHORNE.

Take of chloroform, tincture of opium, tincture of camphor, aromatic spt. of ammonia, of each f ʒiss; oil of cinnamon, gtt. iij.; brandy, f ʒij. Dose, f ʒss, or less, in spasmodic affections of the stomach, cholera, &c. Several practitioners have used this preparation with favourable results in severe cases. — 'Chemist and Druggist,' and 'British American Journal.'

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Untamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

THE MEDICAL CIRCULAR.

WEDNESDAY, DECEMBER 5, 1860.

THE REVOLUTIONS OF SCIENCE.

The revolutions of science are more influential, though, in their beginnings, less remarkable, than those of society. The gestation of a thought proceeds in the silent calm of the closet, and its birth is often unannounced by plaudits or testified by many witnesses. Nevertheless, there is the thought—now a fact, an active, fruitful existence, to grow in a future day to full maturity and strength. There have been great thoughts that have revolutionised the world of action as well as of science—and necessarily so, because the multiform varieties of action in the world are all inspired by one governing principle, modified, it may be, by an antagonising element, which, though subjected, can still turn its sting against its conqueror. Such a thought may govern a nation's life through the entire period of its existence, or it may be overcome by the uprising of a new element, and a nation may live many lives in the course of its career.

As in the theological, so in the natural world, there are two principles which in different societies, and at different times, obtain an ascendency; but neither of them is at any time wholly obliterated. Faith and Reason, Necessity and Free-will, the divine right of Authority and the right of Free Inquiry, are so many phrases representing the same primordial principles as exhibited in the different vocations of men and subjects of thought. We have adverted to the influence of these great masterful thoughts, and the revolutions they breed, in order to bring the subject of our article forcibly before the mind, and to attest the general truth of our proposed argument. This argument has, however, a more limited sphere, and concerns the state and progress of the Science of Medicine alone.

Medicine has been eminently liable to revolutions of this nature. The obscurity and complexity of the phenomena with which it deals, naturally dispose the minds of its followers to rely upon the conclusions of its more distinguished cultivators, and to indulge joyfully in the enthusiasm of faith; whilst, on the other hand, the circumstance that the science is capable of indefinite improvement, and, again, that this improvement must flow from a patient and accurate observation of facts, incite a large number of active and thoughtful men to examine the foundations of every opinion, and to upset the idols of unreasoning credulity.

The simpler the elements of thought, the more permanent and influential are the principles that are established. It happens, however, that in the Science of Medicine the facts are so numerous, so subtle, so comprehensive, so widely related in the regions of natural science, and so difficult of comparison, that the construction of definite laws becomes one of the most laborious and elusive undertakings in which the mind can be engaged. All natural science is subordinate to the science of human life, and, consequently, of disease. Medicine must wait for the advances of her handmaid sciences, before she can herself make any satisfactory progress. She can no more march alone on her career of victory, than can a grand army without its Commissariat. She must be fed by their labours, and pitch her camp where they have marked out the ground and collected the supplies.

Hence the principles, so called, of Medical Science have been, in greater part, merely approximative to fixed truth; and not being absolutely demonstrable, are open to the attack of every bold and plausible speculator. For this reason, the career of Medicine has been a series of revolutions. No other science has been so unsettled, so abundant in theories, so self-contradictory, so prolific of impostors and charlatans.

The present age is peculiarly a transitional one. Iconoclasm is in the ascendant, and no man or school can expect long to retain popularity. The very search after truth which results in the breakage of idols, necessitates the setting up some new object of belief; for Nature cannot endure a vacuum, and the mind of man must rest upon a principle of some sort, or it cannot think; and without thought existence would be void.

Matters have therefore come to this issue, that change is incessant. The science is in full ebullition, and surely we may hope that some cardinal truth will ere long be evolved from the seething mass. It is curious to notice how short-lived are the theories of Physic that are promulgated in these days. Only a few years ago, all fever was said to be caused by local inflammation; and venesection, with calomel and antimony, were the prescribed remedies. During even the culmination of this dogma, there were protestors against it; and we remember well that Dr James Arthur Wilson lingered in the cold shade of disfavour at St. George's Hospital, because he incessantly inculcated the importance of the blood, deprecated useless bleedings, and recommended the administration of salines in lieu of the vigorous practice then almost invariably in vogue. A few years rolled on, and the Profession changed its principles; and in order to make the retreat from a false position decent, a new theory of the change of type of disease was invented. By the majority of Physicians, this theory is considered reasonable; but, in condemnation of its soundness, it unfortunately happens that when there was no alleged change at all, Dr Wilson and a few others raised their manful protest against the practice. Rheumatism was then treated by bleedings *coup sur coup*; the anti-phlebotomists admimistered alkalies and salines; never for a moment dreaming that their particular patients exhibited a different type of disease from that of the patients of other Physicians lying in the same wards: that was a discovery left for a later age.

Now, then, we have a change of type of disease; and in further extension of this dogma, a broader and more radical doctrine has arisen,—that of the non-inflammatory character of inflammatory diseases. In short, there is no such thing as inflammation. As a consequence of this hypothesis, brandy and port-wine are ordered to be administered where venesection *ad deliquium*, and calomel and opium *ter a die*, were formerly the panaceas. So prevalent had become the fashion to stimulate in acute diseases, that we really believe that many Surgeons who were unwilling to abandon their old dogmas, were nevertheless afraid to bleed a patient, lest they should be regarded as old-world Practitioners, or as heinously ignorant of the more advanced principles of Medical Science.

The MEDICAL CIRCULAR has, indeed, given the deathblow to this dogma, as a bit of fetishism; though we should be sorry to imply that advantage had not been derived from a reconsideration of former opinions as to the treatment of febrile inflammatory diseases.

Such is a general view of the rapid transitions which Medical Science is undergoing. If space allowed, we could dilate at great length and with a variety of illustrations upon this topic; but we must forbear. The conclusions we derive from this mode of considering our subject is this: that extremes of doctrine, necessarily leading to extremes of practice, are not consistent with a modest inquisition into the order of nature, and betray an unwise impatience to establish principles which the facts at our command cannot at present justify. Whilst experimental and theoretical Physicians are indulging in these antagonistic hypotheses, let the practical men on whom the preservation of the health and lives of the community depends observe a prudent caution, keeping their suspicions keenly alive, lest they be unwarily fascinated by the attractions of a startling paradox, or the glitter of a great name.

F. C. ALLBUTT, of Caius College, Cambridge, has received the Degree of M.D. of Cambridge University.

SUMMARY OF THE WEEK.

THE RIGHTS OF EMPIRICS.

We last week commented on the decision of the Court of Exchequer with reference to the right of a registered Practitioner to designate himself by the title of "Doctor:" this week we are called upon to comment upon the dictum of a London Magistrate, who has decided, before hearing evidence, that the fact of practice, and together therewith the assumption of the title of Doctor, cannot be construed into the charge that the person so acting *implies* that he is a registered Practitioner. The penalty consequent upon irregular practice depends upon the evidence, that a person alleged to be guilty of it, implies that he is registered under the Act. Now, if the assumption of a registered title, associated with the fact of practice, do not constitute a proof of such an offence, we should like to know the use of the Medical Act? If Mr Selfe's dictum be correct, was there ever a more flagrant deception than this Act has become,—was there ever a greater farce than the proceedings of the Legislature that enacted that measure? Of what earthly use is this Act, if it cannot prevent an ignorant and impudent impostor from calling himself "Doctor," and practising Medicine as if he were a duly-qualified and registered person? This measure cannot be suffered to remain in its present imperfect and incongruous state, and must be reformed. When it was first published, we insisted that it could not possibly work satisfactorily; but our hoodwinked contemporaries deemed us hasty, and affected moderation. They counselled us to give it a trial, as no doubt it might be converted into a useful measure: what do they say about it now? What extravagant laudations can they now pronounce upon our Magna Charta? If Mr Selfe's opinion be a fair inference from the Clauses of the Act, then the Profession have been defrauded of Thirty Thousand Pounds by a most disingenuous trick either of the Legislature or the Colleges.

We advise our brethren to give their attention to this subject, with a view to rectify the wrong, and in the mean time to discard all those unwise and injurious antagonisms between *registered* Practitioners which have lately brought much dissension and no honour to our Profession. The public do not understand our separation of classes and titular distinctions, and smile only at the personal pride of individuals who, though holding the same social and professional rank, affect higher honours. Our numerous Universities and Colleges have fostered these rivalries, and all of us are, from various motives, more or less the slaves of their ordinances and the dupes of their temptations. Though individually, then, we may consent for a time to the bribes thus offered, do not let us, in the name of all that is enlightened and generous, indulge in petty persecutions, and seek to arm ourselves against our neighbour with the poisoned darts of this Medical Act. Though the Colleges divide us, and by such division aim at their own enrichment, do not let us forget the honour of Medical Science, or the dignity and peace of the Profession.

MEDICAL CHARGES.

In a trial reported in another part of our Journal, our readers will see a somewhat singular decision with respect to the right of General Practitioners to charge for journeys in country districts. We have always believed this charge for journeys in addition to medicines to be a universal custom, and are very much surprised to find the right overruled by the Judge of the Chesham County Court. We do not know how the rural Practitioner can be adequately remunerated if this claim be disallowed; for it cannot be expected, in these Homœopathic days, either that the public will swallow unnecessary doses, or allow us to charge extravagant prices for them. Under the Medical Act, a Practitioner is authorised to charge for attendance and medicine; but it is in the power of a Judge to decide upon the equity of individual charges. If this decision should be followed up by others of a similar kind, it will behove General Practitioners to charge for attendance alone, when they can apportion their claim according to the justice of the case. It would be a great advantage if a Convention of Delegates could meet in London to determine this question of Professional charges.

ARSENICAL PAPER-HANGINGS.

The fatal consequences resulting from the colouring of paper-hangings and other decorative articles with the green arsenite of copper have been of late so frequently demonstrated, that we feel it necessary to call upon our readers to exert their best efforts to prevent the use of all articles of furniture coloured with this poisonous substance. The evidence of Dr Hassall and Dr Letheby proves beyond all doubt that many cases of obscure disease, and death itself, are directly traceable to this cause; which is now nearly as common an agent of mischief as lead was found to be a few years ago. Perhaps the general use of gas as an illuminator and warmer has also given an increased intensity to this source of poisoning. If our brethren bear in mind the facts recorded with reference to disease from these causes, they may often be able to explain and cure maladies that now baffle their skill and ingenuity.

THE DRAINS OF BRIGHTON.

Mr Acton has brought down upon himself an avalanche of criticism because he declared that his children were made ill by the foul stinks arising from the bad drainage of a house at Brighton. The Bumbledom of Brighton pretended to be astonished at the accusation, and grew red in the face and shook its fist at the rash calumniator. These indignant officials should remember, however, that this is not the first time that Brighton has been charged with bad drainage; and as the mortality of the town is unduly high, we advise them to imitate the example of other large towns, and appoint a Medical Officer of Health, who will soon point out to them the reforms of which they stand in need, and bring the mortality down to a reasonable standard. This will be a far more sensible course than that of abusing the complainant.

THE CITY ANALYST.

Some weeks since, the Commissioners of Sewers of the City of London appointed Dr Letheby their Analyst, under the powers of the New Act of Parliament for the detection of adulterations of food, and instructed him to report to them as to the best mode of carrying out his duties. That gentleman has recently brought up his Report, in which he has pointed out that there are two classes of adulterations to be provided against: one, that which is pernicious to health; and the other, that which is merely substitutive, and a fraud upon the pocket of the purchaser. There are instances of adulteration in which both evils exist. The Doctor has recommended that the fee should be commuted to a fixed sum of five shillings; and in order that the poor, who are more especially the victims of adulteration, shall not be disabled from enjoying the benefits of the Act by the amount of the fee, he proposes that, where sufficient justification for the analysis may appear beforehand to exist, it should be conducted for them without cost. In all cases where a purchaser intends to submit an article for the investigation of the Analyst, he must inform the dealer of his intention at the time of making the purchase, in order that he may have an opportunity to accompany the purchaser and prevent the substitution of another article. The City Inspectors of Markets will also, in all probability, be empowered to assist Dr Letheby in his operations. We have no doubt that this Act will exercise a beneficial influence in this Metropolis, where there is scarcely an article of consumption sold that is not adulterated. There will, of course, be much difficulty in drawing the line between those articles which are conventional adulterations and innocuous, and those which are injurious to health. Hops at one time was considered a pernicious adulteration of beer, and excited a commotion throughout the country amounting to sedition; but opinion has much altered since that time. Logwood in wine is a substitute, and likewise chicory in coffee: these will require to be treated by the Analyst and the Magistrates in a different manner from cocculus indicus in beer, and chromate of lead in London confectionery. There will be many difficulties in the way, but we trust confidently to the combined good sense and energy of Dr Letheby, the Commissioners, and the Magistrates.

REVIEWS.

The Medical Vocabulary; containing a Concise Explanation of the Terms used in Medicine and its accessory Sciences. By Robert Fowler, M.D.

This is just such a little book as has been for some time in constant request. The rapid progress of the Science of Medicine and the interchange of literature with foreign countries have led to the introduction of numberless terms, the meaning of which the practitioner often finds a difficulty in comprehending. Dictionaries of scientific terms have, indeed, been already published; but they are generally either bulky and expensive volumes, or so brief and jejune as to be unsatisfactory to the student and practitioner. This work is not obnoxious to either objection; it is copious enough to give all the more important phrases, and yet so moderate in size and price as to come within the means of every practitioner. Dr Fowler has exhibited much industry and learning in making this compilation, and we can heartily recommend the work.

The Modern Treatment of Syphilitic Diseases, &c. By Langston Parker, F.R.C.S. 4th Edition.

It is so short a time since we reviewed the third edition of this work, that a long notice of this one would be a work of supererogation.

Anatomy of the Arteries of the Human Body, Descriptive and Surgical, with the Descriptive Anatomy of the Heart. By John Hatch Power, M.D. With Illustrations by B. Wills Richardson, F.R.C.S.I.

This is a new Students' Manual, and is excellently got up, equally in its text, its printing, and its illustrations. The latter, indeed, are admirably distinct; indeed, those of the heart are the best we have seen on the same scale. The book deserves, and no doubt will obtain, a large circulation.

Infant Feeding and its Influence on Life; or, the Causes and Prevention of Infant Mortality. By C. H. F. Routh, M.D.

Dr Routh has attained considerable reputation in connection with the subject of his present work. In this volume he discusses the wide question of Infant Feeding in all its relations, and all accessory sources of information have been laid under contribution to furnish materials for the consideration of the subject. The mortality among infants is usually ascribed to want of breast-milk. We believe that this phrase has been adopted at the instance of the Registrar-General, rather as a convenient way of making a return to that functionary's office than from any scientific confidence in its accuracy. Upon this point Dr Routh remarks:

"It is to the deprivation of this kind of food that the mortality is usually assigned. Now, I believe this is only one of several causes—a powerful one, no doubt, but still it must be obvious from what has preceded that its injurious effects are much exaggerated. This becomes manifest if we look to the actual number of deaths attributable to want of breast-milk, as occurring in a general population, and irrespective of foundling institutions altogether. I have selected the Registrar-General's tables for London. In the quarterly returns, however, under this head, we are referred to cold, atrophy, and privation, as, no doubt, under these heads many cases are included which, properly speaking, should be returned under that of death from want of breast-milk. Perhaps we should include some others, as, for instance, diarrhœa; albeit I make no doubt, when diarrhœa may have been present in most of these cases as a symptom, death has been referred to the cause, want of breast-milk. This is, however, only a supposition; and hence, in the impossibility to measure the amount due to diarrhœa, I am obliged to neglect it. I have, however, to make amends, included all cases of *premature birth and debility* under one year old, which is a large number, but which must needs comprise many who are not thriving under the poor breast-milk given, or the food substituted. Taking the six years, 1849 to 1854 inclusive, it follows that out of 473,865 births in six years, 15,241, or 3·2 per cent., died from want of breast-milk in its widest sense; or, out of 73,227 deaths from all causes, occurring to children under one year old, 20·8 per cent. might be referred to deprivation of this kind of diet.

"My own experience completely bears out these conclusions. I am connected with two institutions which, each in its way, have satisfied me that the congregation of foundlings or children whom it is wished to bring up by hand in towns is almost invariably fatal; so that their distribution, even in circumstances of poverty, is almost always less injurious, and often their salvation.

"An attempt was made in connection with one of these (an infant nursery, where children are received during the day, in the absence of their working parents) to take in boarders; that is to say, the infants of mothers who were engaged as wet nurses. A large nursery,—well aired, scrupulously clean, temperature uniform, 70° usually,—was selected, in which an experienced nurse, directing four or five young women in the arrangement of the children, was placed. The most approved system of diet was enforced, and yet none of these children throve. The mortality was certainly four out of five, if not more. The diseases that prevailed were—diarrhœa, which resisted all treatment; aphthæ or diphtherite, with or without diarrhœa. Lastly, atrophy prevailed largely; it often succeeded the cases of diphtheritis which recovered. Sometimes, however, it was the only symptom present. These children ate enormously, but got thinner and thinner, till at last they died, with all the symptoms of inanition. Usually a removal from the institution led to a recovery; except, however, in cases of atrophy. This disease, once induced, generally persisted, and proved fatal.

"The other institution was a penitentiary for females of a better class, but who, having fallen *once*, were taken in to be confined and reclaimed. Many of these went out as wet nurses. Some of the infants came to the nursery before spoken of; others were brought up by the hand, by *friends* of the patients. Among the latter I could not trace one case of death. Although this statement should be taken with reservation, as after some months the children were lost sight of, still there is no doubt that, although these infants were brought up in circumstances of poverty, and that those who cared for them were often in penury and want, yet they throve better and proved longer lived than our nursery infants. I have no doubt that the causes enumerated by M. Hervieux—the hospital atmosphere, the insufficiency of exercise in the open air—contributed greatly to these results. I might perhaps add another,—the inaptitude of the assistants to the head nurse, and their inexperience of children. I am sure I have seen this in private practice. I have seen a child under the care of a nurse, and that nurse exact, too, in her duties, but not a mother, not having had much experience in the handling of children: that child has pined away, and become weak and thin. An experienced mother has now taken the child in hand; and albeit the same food has been given, and apparently, in as far as regarded external circumstances, the child has been placed exactly as before, it has now thriven well, and recovered health and strength speedily. I cannot measure the extent of this influence by figures, but of its existence and powerful operation I have no doubt.

"To recapitulate, therefore, I have shown—

"1. That for the ages one year and under five, the mortality, even under ordinary circumstances, is in towns nearly double what it is in country; but this difference in the mortality according to residence is nearly seven times as great for foundlings: therefore, foundlings should never be maintained in towns.

"2. That in Ireland, while it is doubtless very high in the first month, for those under one year it is only 30 per cent. in towns, and 22 per cent. in country; the worst mortality with foundlings being 50 per cent.

"3. That travelling in fair seasons is not dangerous to foundlings.

"4. That the mortality is greatest in spring, and least in autumn, with children in public institutions.

"5. That the chief cause in the mortality of foundlings is want of exercise, and the abuse of the recumbent position.

"6. That want of breast-milk will only account for a mortality of 3·4 per cent. additional.

"7. That a depraved hospital atmosphere and certain endemic contagious disorders are the chief causes of the mortality in foundling hospitals.

"From which results we are justified in concluding—(*a*) That if foundling hospitals are to be maintained at all, they should always be built in the country. (*b*) That large open single wards should be converted into small well-ventilated rooms, capable of containing from three to four cots, with one nurse at least to each small ward so constructed. (*c*) That where it can be done, and wet nurses can be supplied, preference, if possible, should be given to the children's mothers. (*d*) That means should be taken to insure the proper exercise of the infants."

We cannot, of course, in the brief notice our pages enable us to give, reproduce all the views promulgated by Dr Routh. We shall, therefore, content ourselves with adding to the foregoing quotation another description of the Author's views on substitutes for the mother's milk.

"Having now dwelt upon that class of cases where the mother is either able, or can be made able to suckle her own child, we pass on to the second inquiry referred to, viz.—If she be not able to wet-nurse the child at all, certain principles ought to be observed in feeding it, whether the artificial food given be animal milks or something more distinctly artificial, leaving the employment of a wet nurse as a *pis aller*.

"In those cases where we are compelled to bring up a child by hand, there is the greatest need of care and judgment. Prior to eight months the difficulty is considerably enhanced. At that period teeth are generally present, the anatomical conformation of the alimentary canal is well-nigh completed, and the child is able to digest even vegetable materials. But in the earlier periods, and particularly in the first three months of existence, the danger of death under artificial feeding is very great: most of the tables above given prove this. This is especially true for illegitimate children. In a table drawn out by Mr Acton in his paper before referred to, the chance of death at this period amongst illegitimate children, such children being generally brought up by hand, is about one-third of all the deaths in the year: thus out of 326 children, 31 died under 1 week, 45 above one week and under 1 month, 110 under 3 months, 74 under 6 months, 27 under 9 months, 39 under 1 year.

"Now I believe that no treatment can be safely recommended in these cases which can bear any comparison with that which experience has proved to be most successful in other countries: I allude to the direct suckling of the child from the breast of some other animal, as for instance the goat, to which I have already referred. Besides, it is the most natural. This itself is no small advantage. But it also does away with the necessity of an experienced nurse to prepare the child's food *secundum artis* [*sic*], so that it shall not disagree. Lastly, no improper practices of the animal are likely to endanger the safety of the child, which, after suckling a short time, it will come to love and protect as its own offspring.

"Undoubtedly, therefore, the plan has experience to recommend it. But more than this; I have already shown that by properly feeding these animals we may obtain from them, as well as from cows, a milk which shall so closely resemble human milk as scarcely to be distinguishable from it even by chemical examination. The particular disadvantage which attaches to the employment of milk as it is usually obtained from cows, even when free from adulteration, is thus obtained. Very fresh milk undoubtedly agrees best with children. Now it has occurred to me more than once that the explanation may be possibly given, namely, that the milk when warm, precisely as it is with blood, loses by evaporation some vital volatile principle, and is thus rendered more difficult of digestion. In confirmation of this view it may be stated, that the existence of such volatile principles as I have before stated has been proved incontrovertibly by the experiments of Parmentier and Deyeux, although

unfortunately their chemical composition has not been made out. With the intention of making this out, they distilled frequently several specimens of milk. Speaking of the distilled product, they remark: 'It would be a mistake to condemn the distilled water of milk as simply water. Its smell, taste, and especially the ready manner in which it is changed by exposure, prove evidently that it holds in solution one or many substances. But what are these substances? This is indeed a difficult problem to solve. All that is possible at present to say is, that these substances are easily decomposed, since we find their remains in the water which contained them; they are those remains which affect the transparency of this fluid, and give it that viscosity and putrid odour which it acquires after a time.' Messrs Parmentier and Deyeux believe this product to be analogous to those obtained by the distillation of muscle, urine, blood, lymph, and albumen, which also as readily decompose. The volatile principles are occasionally affected by the aliment previously taken; particularly by some, though not by all those of an aromatic character: but they are, nevertheless, always present, and obtainable from milk. Ferris proved that ammonia constituted no part of these principles, nor was it evolved during any period of its decomposition.

"So far, however, it may be conceded, that there are some volatile principles which escape from milk during exposure to the air. We have an analogous example in the case of the blood. Where blood is first drawn it is perfectly fluid, and could be safely injected into the veins of another animal of the same species. If, however, it is allowed to remain for a few minutes aside, it coagulates, separating into clot and serum. Dr B. W. Richardson has shown that this change depends upon the escape of ammonia, which holds the fibrin in solution. Now it is a remarkable fact, that new milk has a much stronger odour *sui generis* when first drawn than after it has been kept for a time and is cool. Moreover, we are all aware (more particularly in reference to cow's milk, although the same truth applies in a lesser degree to other kinds of milk) that exposure to air causes it to become acid, from lactic acid fermentation; and this, as before seen, is one of the causes of the diarrhœa and other abdominal discomforts so commonly observed among children. On this supposition two popular customs may be explained. First, that boiled milk does not agree so well with children as milk which has not undergone this process, because the volatile principle, whatever it be, has been expelled by the boiling. Secondly, and no doubt, also, this is the reason why, when ass's milk is ordered, the animal is brought to the door and usually milked immediately before the milk is taken. As in the case of the blood, which when coagulated may be said to have lost its vitality, so it may be with the milk. It can, therefore, be no matter of wonder, that as milk is usually obtained in towns, even when it is perfectly unadulterated, yet, by reason of the necessary exposure to which it must have been submitted, it so commonly disagrees with children; while in the country, where it is usually given very soon after it has been drawn, it agrees so well.

"There is another reason also why milk as usually obtained in towns should be unwholesome. It is a matter of common observation, that there is much difficulty in bringing milk by the railways into London, the very agitation of it causing it to be decomposed, and tending to the production of butter and buttermilk. To obviate this inconvenience, all sorts of methods (and some of these are very ingenious) to prevent agitation have been adopted. Still it must be obvious, that even the transport of cold milk in a cart some two or three miles only must be attended with this alteration of the intimate chemical union of its elements, and particularly so, as I before stated, when the milk has been previously watered, which circumstance favours the operation of the cream. The objection is not a solid one which would deny that milk can be so deteriorated because it is nevertheless occasionally found to be *nutritious* to a child. The ordinary black pudding, and even meat, is nutritious; yet in both these cases change, by which all volatile products have been expelled, has taken place. But adults have powers which infants may not possess of *assimilating* these substances. The same is true of milk. Some children may also have a stronger digestion than others. But as a rule,—and precisely as they have very little power of generating heat, while adults have a good deal,—so to children these volatile principles may be essential to the requirements of their organism, while to adults and to some stronger children they may be superfluous. Whatever be the cause, the fact is incontrovertible—the newer the milk is, the better it is for the child; and it points most distinctly to the absolute necessity of allowing the milk to remain as short a time as possible exposed to the air before it is given to the child; and therefore is evidence of the immense advantage which would accrue by allowing all infants to take the milk directly from the nipple of the animal. Acting under the knowledge of these difficulties, whenever a child is being brought up by hand, and it is practicable, I always recommend that the cow, like the ass, should be brought to the door, and then and there milked, and the milk in its fresh state at once given to the child. It is remarkable how well some children will thrive under this mode of procedure, when other means have failed."

We need scarcely add that Dr Routh is not friendly to the employment of the various substitutes for an animal diet. This work should be perused by every practitioner, as, apart from some of the peculiar views maintained by Dr Routh, it is replete with valuable information.

Register of Obstetric Cases. London: John Smith & Co., Medical Stationers, 52 Long Acre.

Mr Smith has provided a skeleton Table for filling up with the details of his Midwifery Cases by the private or public practitioner. It cannot fail to be useful.

The Levant Quarterly Review of Literature and Science. Edited by R. F. Foote, M.D. Constantinople.

We are glad to see our old contributor Dr Foote engaged in promoting British Literature in the Turkish Capital. This, which is the second number, contains an able article, by the Editor, on Quarantine in the Levant: the other articles chiefly belong to general science and literature. This is an encouraging sign of mental activity and the progress of English literature in the East, and does much credit to Dr Foote.

GENERAL CORRESPONDENCE.

POLICE LAW.

To the Editor of the Medical Circular.

SIR,—A few days ago I applied by solicitor to Mr Selfe, the presiding magistrate at the Thames Police Court, for a summons, under the new Medical Act, against a notorious quack in the neighbourhood, who styles himself Doctor—publicly professing to give "Medical and Surgical Advice in all cases;" and, moreover, we were prepared with no less than three witnesses for whom he had "prescribed as a medical man, and taken money in each case" for so doing.

Mr Selfe then, to our utter astonishment, made the following monstrous and illogical remarks:—"That none of these things 'implied' that he was 'registered under the Act;' and that if any man did not wish or induce the public to imply that he was registered under the Act, he was then at perfect liberty to assume any name or title he thought proper, whether that of Doctor or Surgeon."

Seeing that my solicitor made very little attempt to argue the case and upset this dogma and rubbishing opinion, I was about to venture to do so myself, when I was interrupted by the magistrate, and politely informed that "I had already heard his opinion; but that if, after hearing that, I still felt disposed to summon, he would grant me one; but in the event of a non-conviction he should certainly saddle me with all expenses, which I could see would be only fair."

After this shortsighted and onesided prejudgment of the case, I naturally came to the conclusion, with Mr Young, my solicitor, that before such a magistrate, with his mind already fully made up, any attempt for the suppression of quackery, either in the interests of the public health or in those of the Profession, would be only like throwing money away, and therefore declined.

It was not only a most unlikely case, but simply an absurdity to suppose any man (in his senses) would be foolish enough to "make a noose for his own neck," by publicly asserting himself to be qualified and registered, when he was not; because by so doing he would not only be criminating himself, but putting the public on their guard against himself, and so, in proportion, "shutting out custom."

Let us, however, Mr Editor, be thankful that if such be the state of things in our Police Courts, we have still the County Courts and the Apothecaries Act of 1815 to fight this Hydra-headed and Argus-eyed monster, Illegal Practice, with!

You are at liberty to make what use you please of the blessed uncertainty of our "Medical Laws."

I am, Sir, &c.,

M. COLEMAN, L.R.C.P. Ed., M.R.C.S. Eng.

265 Whitechapel road, Nov. 28.

HOSPITAL REPORTS.

GUY'S HOSPITAL.

CHLOROSIS.

We are indebted to Mr Henry Hutchings' notes for the following cases.

Elizabeth Woodford, æt. twenty-one, servant, admitted into Mary Ward, Guy's Hospital, Jan. 25th, 1860, under the care of Dr Gull. Has been residing at 39 Old 'Change. She is a well-made, rather good-looking young woman, without any evident signs of strumous disease. She now presents an extremely anæmic and pallid appearance; has always enjoyed good health, until five months since, when she began to suffer from weakness and palpitation of the heart; (has never had rheumatic fever;) catamenia regular, but scanty; urine variable in colour, but not albumineus; bowels constipated; appetite bad; tongue pale and flabby; no cough or expectoration; pain in back part of head, occasionally acute; pulse very feeble; has suffered from leucorrhœa, but is at present free from such discharge. No dulness on percussion; but there is a chlorotic mitral murmur laterally.

26th.—Pil. aloes cum myrrhâ, gra. v., om. n. s. ℞ Tr. ferri sesquichlorid., ℥ x.; tr. calumb., ʒss.; ex aq. menthæ, ʒj.—bis die. Middle diet.

Feb. 2nd. — Better. Capt. pil. ij. om. n. Middle diet. Pergat. mistura.

10th.—Better. Perst. mistur. Bowels still conatipated. Pil. aloes cum myrrhâ, grs. xv., om. n. s. (Aspect of countenance much improved.)

21st.—Much improved. Pergat. medic.

24th.—Omitt. mist. et pil., et habeat decoct. aloes co., ʒij.; sp. amm. co., ʒss.; mist. ferri comp. ad ʒj.—ter in die. semend.

28th.—Better. Pergat. Chops daily.

March 6th.—Improving. Looking much better.

16th.—Better. Perst.

21st.—Quite well. Discharged cured.

PARAPLEGIA.

Martha Wakeley, æt. forty-six, married, residing at Boon yard, Bishopsgate street, admitted into Mary Ward, Guy's Hospital, Jan. 25th, 1860, under the care of Dr Gull, suffering from paraplegia of six months' duration. She states that she has been married for twenty-three years, but has never borne any children. She was always regular with her monthly periods, and passed the change six years since, at which period she did not suffer much. She has always enjoyed good health, until six months since, when a loss of sensation began at the extremity of each toe, which has gradually extended upwards. Loss of sensation entire below the knee-joint, and very imperfect above. Now complains of great debility, and of similar feelings commencing at tips of fingers, with some little numbness in the hands. Has never received any blow, or other injury. Bowels constipated; no incontinence of urine; has been under the treatment of a surgeon for some time without gaining any benefit.

Jan. 26th.—℞ Pil. coloc. co., gr. v., om. n. s. ℞ Tr. valer. volat., ʒj.; ex aq. camph., ʒj.—ter die sum.

Feb. 2nd.—Lin. belladon. spin. applicand.

10th.—Much the same. Perst. mist. et lin. Pil. rhæi comp., gr. v., pro re natâ.

15th.—Omitt. med. Tr. cinch., ʒj.; ex decoct. cinch., ʒj.—ter die.

21st.—Much the same. Pergat.

28th.—The same. Omitt. lin. belladon. Ung. antim. pet. tart., ℥ss., pro applicatione.

March 6th.—No better. Pergat.

March 16th.—The same. Pergat.

20th.—In the same condition.

April 28th.—Has continued in the same state since the last date, and was to-day discharged relieved.

CHOREA.

Mary Ann Sharman, æt. twelve, admitted into Mary Ward, Guy's Hospital, Jan. 23rd, 1860, under the care of Dr Gull, suffering from chorea of two weeks' duration. Her mother states that, a fortnight since, she was placed in a dark room and frightened—the symptoms of chorea coming on immediately after. Has never had rheumatic fever. She is a light-haired, delicate-looking little girl. Pupils widely dilated; heart's rhythm inconstant; systolic murmur when the heart's action is quickened by choraic movements; pulse 112. To be strictly watched, and kept at rest. Brandy, ℥ij.; bread, milk, and arrowroot, *ad libitum*.

26th.—Much the same. Pergat.

February 2nd.—Slight improvement. Pergat. ℞ Pulv. rhæi salin., ℥ss., hor. n. s.

10th.—Better. Heart's action more regular. Pergat. remedia.

18th.—Much improved. Pergat., et habeat vini Xerici quatuor uncias quotidie.

21st.—Pergat.

28th.—Improving. Pergat.

March 6th.—Better. Pergat.

16th.—Convalascent. Pergat. remedia.

17th.—Her friends wish to take her home. Discharged cured.

CHLOROSIS.

Marianne Clarke, æt. twenty, admitted under Dr Barlow, October 26, into Lydia Ward. Up to the last nine months she lived at Budeland, Shropshire, considered a healthy place. Since she has been in service at Leytonstone, which is a damp place, surrounded by large woods. Her mother is not a very strong woman. She is subject to various pains and ulcers on the legs. Her two elder sisters have been similarly affected to herself, but are now well. This patient had generally good health and some colour in her cheeks until eighteen years old. She then began to menstruate. She had not been well for some time time previously to her first menstrual period. The discharge was moderate in quantity, and without pain. Since, she has been regular only for three or four months at a time. No vicarious hæmorrhage. The discharge has been scanty, and continues upon her three or four days: no pain with it. Has had leucorrhœa occasionally, but not lately. Has lost her colour gradually since the first menstrual period. She has pains in the chest and across the back; also globus hystericus, giddiness, noises in the head, shortness of breathing, coldness of extremities; palpitation after exertion, and also on lying down or going to bed. She has also always been subject to bilious headache, and to vomiting. In the beginning of the year she consulted a medical man for these ailments, and also for a severe cough. She has no cough now. She got better under, as is supposed, the administration of mist. ferri co. in about two months, and became regular in her periods of menstruation. On admission into hospital, had not menstruated for two months. She appears a pale, chlorotic girl; dark hair and eyes, with an unconcerned, phlegmatic look and manner. No appearance of defective nutrition. The mammæ are full and well developed. She has a high forehead; lips look anæmic; tongue pale, clean, and moist—she complains of its being parched and dry in the morning. There is a loud blow audible in the arteries of the neck, but no distinct *bruit de diable*. The chest is normally resonant, and respiratory murmur natural. Systolic *bruit*, rather rough—audible, especially at the junction of the third costal cartilage with the sternum, extending upwards and externally for a short distance. Pulse 72, compressible (hæmorrhagic). Appetite good—urine natural—bowels regular—no nausea or sickness.

Oct. 26th.—℞ Mist. ferri co. ter die, ante cibum.

Nov. 14th.—Her cheeks gradually acquired colour, and she became stronger; but no appearance of menstruation. Bowels confined. ℞ Pil. aloes cum myrrhâ, grs. xv., om. noct. h. somn.

Presented, relieved.

We are indebted for the above to the notes of Mr Hilton Fagg.

CHOREA.

Emma Magan, æt. twenty, a servant-of-all-work, married six months, residing in the City road, was admitted on February 1st, under the care of Dr Barlow, into Lydia Ward. Her health has always been delicate. She has been subject to winter coughs, &c. Has worked hard, and been much exposed to cold and wet. Her father was subject to rheumatism; grandfather phthisical; her mother suffered during first pregnancy from chorea. One of her sisters died from cardiac disease and dropsy. Six years ago she was in this hospital for an attack of chorea, which lasted four months. She has also suffered from headache and occasional pains in the limbs. No history given of any rheumatic attack. About two months ago she had slight choraic attacks, affecting the right side only. These returned again a fortnight after; they passed off. A month before admission to hospital, the present attack commenced by symptoms of involuntary movements, affecting the right leg. They soon after disappeared on the right side, to become fixed on the left side of the body. Articulation became impeded, but this symptom left within a week of admission. She has not menstruated the last six weeks, but was always regular before. She appeared, on admission, an anæmic, unhealthy-looking girl. Pulse 90, regular, slightly sharp or jerking; chest unusually resonant on percussion; respiratory sounds healthy on auscultation; a slight systolic *bruit* is audible, most distinct in the space between the third and fourth costal cartilages, appearing a roughened prolongation of the first sound. This is also slightly audible on the course of the aorta, not to be heard in the axilla. The second sound is clear. Tongue clean; bowels regular. She has morning sickness, and complains of headache (as marked mammary signs of early pregnancy). The muscular movements are of a clonic character, affecting only the left side and the muscles of the face; the movements are neither violent nor very frequent, and cease altogether during sleep.

Feb. 1st.—℞ Zinci sulph., gr. j.; res. galban. co., gr. v. ter die. Middle diet.

3rd.—Involuntary movements continue, but are less frequent on the left side.

7th.—She was very sick this morning, otherwise improving.

10th.—Much the same. Augeat dos. ferri sulph. ad gr. ij.

15th.—She has vomited the last three mornings; feels much stronger; movements steadier.

17th.—Improving. No mammary secretion; urine, on standing for a few days, shows an opaque, yellowish-white pellicle formed on its surface, with a strong lacteal or cherry odour, presenting under the microscope the appearance of minute granular globular matter from a day after formation. The pellicle broke up and subsided in irregular masses (*kiestien*).

18th.—Is now able to use the left hand, and was presented much relieved.

We are indebted to the notes of Mr John Henry Galton, Clinical Clerk, for the above case.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 27, 1860.

Mr SKEY, President, in the Chair.

A paper, by Dr HANDFIELD JONES, was read on a case of

PROPTOSIS WITH BRONCHOCELE.

The patient, C. B., a female, aged forty, had been on two occasions under Dr H. Jones's care, suffering with excessive prostration induced by overwork. She had also proptosis, vomiting, cough, palpitation, and enlargement of the thyroid. The symptoms were usually aggravated at night. On the first occasion the throbbing and distension of the gland were so distressing, that the question of ligaturing the arteries was entertained. Iodine, internally and externally, had no effect in diminishing the goître, and leeches gave very temporary relief. The debility was so great during both illnesses, that she was in considerable danger. Sedatives, succeeded by tonics, restored her on the first occasion, and the application of ice to the neck induced considerable diminution of the goître. In the second attack, which occurred about a year after the first, the very free administration of opium, and afterwards of strychnine, restored her, and that rather rapidly. Country air was also most markedly beneficial. The proptosis disappeared or greatly lessened as her general state improved. The view taken by Dr Jones was that the fundamental malady was debility, especially of the nervous system, which, by affecting various vaso-motor nerves, gave rise to the several symptoms. Thus, effusion behind the globe of the eye would cause proptosis; hyperæmia, and increased cell-action of the thyroid vesicles, would produce goître; paresis of the vagi would give rise to palpitation and vomiting. The benefit derived from tonic remedies strongly corroborated this view.

Dr C. J. B. WILLIAMS said that the case brought forward by the Author was one of a curious and interesting nature. He had seen a considerable number of such, and had felt especial interest in the investigation of their peculiar symptoms. The enlargement of the thyroid gland, although usually present, was not always so. The symptom which he had noticed as being constantly present was an enlargement and throbbing of the arterial system of the head and neck. It had been noticed by a writer in one of the Dublin journals, about fifteen years ago, that the arteries in these cases not only appeared larger, but were in reality very greatly dilated. This observation he (Dr Williams) could fully confirm. He believed that the tumefaction of the thyroid body was due to dilated blood-vessels, chiefly arterial, and that it did not depend, as in other forms of bronchocele, upon the increase of solid structures. The proptosis, he thought, might also be explained by the distended conditions of the arteries behind the globe; and he believed that those of the brain itself would be found in a similar state. To this distension of the cerebral vessels was no doubt due the feelings of distension, throbbing, &c., in the head, which constitute so marked a feature. At first sight, it might be thought that with such an excess of arterial action, a depleting system was the one indicated; but, as we now well knew, dilatation of the arteries does not really indicate excess of action, but simply diminished tonicity of their coats. He could most fully confirm the opinions expressed by the writer of the paper, as to the advantages to be gained by tonics. He had found iron by far the best of these remedies, and was accustomed to give it in its more astringent form, and in combination with free acids. He mentioned several cases, in some detail, in which at first he had felt hesitation in prescribing tonics, but all of which had derived the greatest benefit from their use. He adverted to the fact, that as far as his observations went, this peculiar combination of symptoms occurred only in females. He had never had the opportunity of making an examination after death, and expressed a hope that any who might in future have such, would not neglect to carefully ascertain the actual condition of the arterial system.

Mr SOLLY mentioned a case which he believed was unusual, in which the disease affected only one eye. In reply to a question from Dr Quain, Mr Solly stated that there was no bronchocele.

Dr MERYON gave the details of a remarkable case in which the symptoms had been well-marked and severe, and the subject of which was a man. In this instance the patient, a gentleman, aged forty, had suffered so extremely from prostration with head symptoms that he had often not been expected to live. He had been seen in consultation by Sir Benjamin Brodie, Dr Chambers, and several others. It had been noticed in his case, that when the thyroid diminished the proptosis became more marked, and the use of iodides, and of the iodide of iron, had appeared to be injurious rather than beneficial. He had ultimately been cured by a change of air, and was now in good health, his bronchocele being now of considerable size.

Mr HOLTHOUSE adverted particularly to the explanation of the cause of proptosis. He could not agree in thinking that it had anything to do with relaxation of the muscles of the eye, a theory which had been proposed. In cases in which the third nerve was paralysed, and the muscles therefore relaxed, proptosis, he said, did not occur. He thought that there must in many cases be more or less of serous effusion behind the

globes. In one or two cases on record, organic disease of the heart had been found after death.

Dr Dickson confirmed Dr Williams' observations as to the usefulness of iron in these affections. He adverted to the recurrence of proptosis in cases of extreme anæmia in connection with mania, and stated that he had observed many cases in which it was a prominent symptom, and had preceded the development of more serious ones. He referred to Dr Gooch's observation on the false hydrocephalus of children, and related an interesting instance, which had occurred under his own care, in which the change of treatment from a somewhat lowering one to one of an opposite character had rapidly removed head symptoms which had at first been alarming. The patient was a young lady, who had been much overworked at her studies.

The Author of the paper, in his reply, related the particulars of a case, in which a girl, who had proptosis and goître, was liable to palpitation, occurring in paroxysms, in one of which she died. At the autopsy her lungs were found in a state of red hepatisation, which condition he considered to have arisen from paresis of the pulmonary plexuses.

A paper, by Dr A. Wynn Williams, was read, on

THE TREATMENT OF SCROFULOUS DISEASES OF BONE AND OTHER TISSUES,

of which the following is an abstract. The Author, after a few preliminary remarks, stated that scrofula is very prevalent in the county of Carnarvon and the whole of North Wales, caused in a great measure by the intermarriages of relatives in thinly-populated villages, and by the bleak and mountainous districts in which the inhabitants reside, and to the want of proper nourishment, especially animal food; that scrofula of the external parts of the body is more common in the light-haired inhabitants than in the dark, probably due to their skin perspiring more readily, and being more easily affected by sudden atmospheric changes; but that this remark did not apply to scrofulous disease of the internal organs, considering phthisis to bescrofula of the lnug: he was inclined to think that the dark were more liable to disease of these organs than the light. The Author stated that he had of late years applied a weak solution of iodine in all scrofulous diseases, not only of the external parts, as the skin, &c., but also of the internal, as bone, &c. The solution varied in strength, from a drachm to four of tiucture of iodine, in eight ounces of water. When applied stronger it is apt to inflame and even blister the skin. A piece of lint well saturated with the solution is laid on the diseased part, and covered over with oiled silk, &c., to prevent outward evaporation of the iodine. The lint of a dark purple colour, when placed over an ulcer, presently becomes white, owing to the evaporation and absorption of the iodine, the part in contact with the wound first losing its colour. The same occurs when there is no wound, but takes place more gradually and equally from all parts. That iodine when applied in this manner is absorbed, there can be no doubt; for if a stronger solution is applied, it irritates and inflames the skin, stopping up its pores, so that the iodine can no longer be absorbed, as is evidenced by the lint when removed not being altered in colour. He also stated that when there was much pain or tenderness, he used strong iodine paint as a counter-irritant. When the existence of pus had been ascertained, whether in a joint or elsewhere, he made a free incision, so as to give ready exit to it. After the evacuation of the pus, the iodine lotion was applied immediately to the diseased part, as, independent of its therapeutic action, its antiseptic properties were of great advantage. He had found the following lotion, when applied to unhealthy, gelatinous-looking granulations, very efficacious in setting up healthy action. ℞ Potassii Bromidi, Potassæ Chloratis, āā ℥ij.; aquæ, ℥viij. The Author dwelt particularly on the necessity of keeping the parts at rest, remarking that in phthisis the work of the lungs should be diminished as much as practicable, and that any agent which increased their action must be injurious; that we should endeavour, by suitable remedies, to excite increased action those organs which act vicariously to the lungs. He considered that presenting more oxygen to the lungs than is contained in the ordinary state of the atmosphere was likely to be injurious rather than beneficial; but he considered it might be advantageously presented to the blood through the skin and mucous membrane of the alimentary canal: that the beneficial effect of rest was well marked in strumous affections of the cervical glands, as these affections get well much more rapidly when kept as motionless as possible, by means of air or other light cushions. For the purpose of rendering motionless a diseased joint, he recommended leather or gutta-percha splints, preferring the former. As regarded internal remedies, the Author prescribed a nutritious diet, consisting, amongst other things, of at least one meal per diem of well-fed animal food, and porter or wine, with cod-liver oil, or a little rum beat up with an egg and milk, or with cream; the administration of either citrate of iron and quinine or syrup of iodide of iron with calumba, stating that when practising in Wales he was in the habit of ordering a grain or two of iodide of potassium to be taken in a tumblerful or more of the Water of King Arthur's Well,—a powerful chalybeate, containing carbonate of iron held in solution by excess of carbonic acid. When there was any tendency to diarrhœa, aromatic confection, with tincture of opium and decoction of bark; if excessive, the compound kino powder.

The paper then proceeded to narrate the particulars of seven cases in which the good effects of the plan of treatment recommended had been well marked. These cases comprised instances of scrofulous affections of various kinds—some in which the bones of the spine or those of the larger joints had been affected.

The Author remarked that iodine had been considered by many a disinfectant. The Academy of Medicine of Paris have, however, lately decided that it is not a disinfectant; but that the smell is made to cease by the iodine setting up healthy action in the diseased parts, so that the discharge itself ceases to be offensive. They do not, however, state how this healthy action is produced. The Author's own impression is, that iodine, bromine, and perhaps chlorine, and their salts, act directly—probably chemically—on certain abnormal deposits, and it is thus iodine acts on strumous deposits, rendering them more soluble, and so enabling them, when there is no external wound, to be removed by the absorbents; when there is an external opening, enabling them to be discharged with the pus like any other foreign body. The obnoxious matter being thus got rid of, Nature is allowed to carry on and complete the process of repair. The Author stated that he believed that if the above modes of treatment were fully and fairly carried out, particularly in the commencement of scrofulous diseases, we should hear less of excisions of joints than we do at the present time. He did not mean to say that they would entirely supersede the use of the knife; but he trusted he had shown by the results of the cases detailed that he had not without reason come to the conclusion that the number of cases in which it would be necessary to have recourse to it would be very much diminished.

Dr Webster stated that he had been interested in learning that Dr Wynn Williams had observed that scrofula was more frequent in the fair-complexioned, since he, Dr Webster, had arrived at the same conclusion. He believed, however, that the liability to scrofula had a very close connection with the dietetic habits of the community. Scrofula was not rare in persons of dark complexion, if they were confined to vegetable aliment. In a recent visit to Spain he had been much struck with the fact that although the dark temperament very largely predominated, yet the various forms of scrofula were very common. He attributed it to the fact that the Spaniards, as a race, lived almost exclusively on vegetable food. He believed that the principal point in the treatment of scrofula was attention to diet; and he wished to ask the Author of the paper whether, in the cases in which he believed that the iodine lotion had exhibited such remarkable efficacy, he had not also employed dietetic and tonic methods of treatment at the same time.

Dr Wynn Williams replied that in most of the cases the patients had been put on good diet and had taken cod-liver oil.

Mr Henry Thompson adverted to the vagueness of the term Scrofula, as generally applied. He believed that it was applied very often to designate diseases which were simply those of cachexia and debility. He had for many years been in the habit of applying the iodine solution in exactly the same manner as recommended by the Author of the paper, whose statements as to its efficacy he could fully confirm. He considered that spongio piline was the best material on which to apply the solution. He considered the solution to be decidedly preferable to ointments.

A paper, by Mr Buck, of Crewe, was next read, being the narration of a

CASE OF MALFORMATION OF THE BLADDER AND GENITAL ORGANS.

The subject of the case had died at the age of seventy-three, from acute bronchitis; and as rumours had been afloat as to malformation of his genital organs, Mr Buck seized the opportunity for making an examination. The post-mortem was, however, conducted very hurriedly, and under great disadvantages. The individual, during life, had at home dressed as a woman, but when away from home had assumed male attire, and even acquired some celebrity as a prize-fighter. The corpse much more resembled that of a man than a woman, the hair being short and strong, and there being several days' growth of beard. The mammæ were quite undeveloped, and there was a considerable growth of hair on the chest. On the pubic region was an opening which communicated with what existed of bladder; the ureters opening on the exposed surface. There was no penis, but three folds of skin occupied its place, lying one over another. In what resembled the labia, on each side were lodged the testes, in a partially developed state, with vasa deferentia passing up to the cellular tissue in the pubic region.

The Author apologised to the Society for the imperfection of the dissection.

OUR NOTE BOOK.

SWALLOWING INDIGESTIBLE SUBSTANCES.

Dr Read exhibited at the Boston Society for Medical Improvement a quantity of stones, varying in size from that of a pea to that of a cherry, which had passed through the intestinal canal of a boy seven years old. Having seen one of the performers at a circus swallow or pretend to swallow stones, he resolved to follow his example, and in the course of one afternoon he swallowed *sixty-four*, the united weight of which was a little more than nine ounces, and which filled an eight-ounce bottle.

On the next day the stones could be felt through the walls of the abdomen, and upon percussion could be heard to rattle but produce no inconvenience; castor-oil was administered, and they were readily expelled.

At the same meeting, the proceedings of which are reported in the 'Boston Medical and Surgical Journal,' Dr Tyler said that it was a common thing for patients at the McLean Insane Asylum to swallow small objects, such as pieces of glass, coal, stone, thimbles, &c. Recently a woman swallowed a crochet needle, which was voided without inconvenience. Among some of the patients was a curious propensity to swallow toads, and there is now in the Asylum a man who has swallowed half-a-dozen live toads without injury.

Dr Adams stated that in a case of obstruction of the bowels, which followed the eating of a large quantity of cherries and swallowing the stones, the nurse collected and counted *one thousand and seventy-seven* cherry-stones which were evacuated.

Dr Agnew, of this city, has in his private collection a preparation of the stomach and intestines of an insane patient in which are accumulated an extraordinary variety of foreign materials, among which we recollect having seen long strips of bandage, suspenders, portions of clothing, buttons, &c.—'Medical and Surgical Reporter.'

HOT AIR AND CARBONIC ACID BATHS.

A recent article in the 'Journal of Practical Medicine and Surgery' (Art. 5,883), in which the therapeutic properties of carbonic acid gas are referred to, suggests an explanation, which had not before occurred to me, of an empirical method of treatment I have long been in the habit of applying in rheumatism. It is a very simple kind of hot-air bath, which I have often found highly beneficial, and is administered as follows:

The patient undresses entirely, and lies down on a couch; he is then covered with a sheet and blanket supported by hoops at a distance of about eighteen inches from the body. An earthenware vessel, containing a lighted candle five inches in length, is then placed between the legs, the edge of the sheet being raised in one point to admit a quantity of air sufficient to supply materials for combustion. Copious perspiration generally ensues in less than half an hour, and when the taper ceases to burn, the patient is removed to another bed, where diaphoresis continues, and sound sleep follows. Rheumatic pains are frequently cured by two such baths.

Now the carbonic acid evolved during the combustion of the taper appears to me to claim a most important share in the results of the medication, hot air and steam alone being incapable of producing such powerful effects.—Dr Faivre D'Esnans, Physician of the Hospital of Baume-les-Dames (Doubs).

ON THE DISEASES OF PRINTERS.

Dr Van Holsbeek having enumerated the diseases resulting from overwork, from intemperance, want of cleanliness, vicious habits, protracted watching, &c., proceeds to speak of the morbid affections more especially belonging to the printer's art. Fissures of the lips, of varying depths, are of frequent occurrence; at other times tumours are developed on the inner surface of the same parts, which are nothing else than follicles whose excretory ducts are closed. These tumours sometimes inflame, become highly painful, rapidly ulcerate, and assume a cancerous appearance. Such affections of the lip are owing to the habit some compositors have of putting into their mouth the types still moist with the fluid which has served to wash them. Dyspepsia is frequent, as is diarrhœa; the latter is, however, of a transitory and mild nature. Among the most common affections are those of the respiratory passages, of which laryngitis and bronchitis are the principal; pleuritis is rare; pleuro-pneumonia is frequent and severe. These diseases are favoured by the curved position which the printers are obliged to maintain during their work, particularly when they correct on the forms, and still more by the nightwork, by gaslight, by the dust and emanations in places often confined and badly ventilated. Nearly 25 per cent. of printers die of tuberculosis, either hereditary or acquired. Diseases of the heart prevail among the pressmen; hæmorrhoids are rare; varices and varicose ulcers are of frequent occurrence; the compositora who correct on the form frequently suffer from cerebral congestions and hæmorrhage. Among nervous diseases we observe tremor of the hands, against which the Author successfully employs the electric current. Saturnine colic and paralysis are rarer than formerly, an improvement due principally to the difference in the composition of the materials of which the type is made, to the precaution of cleaning it from dust, as well as frequently rubbing the boxes which contain it; lastly, to the care of the workmen, who no longer put the letters in their mouth. Hernia is common, particularly among the pressmen; in them we occasionally observe distortion of the joints of the fingers. Fissures and callosities form on the thumb and index-finger of the right hand, on account of the roughness of the characters, particularly if they are new and damp with the matters with which they are polished; moreover, in consequence of the habit the printers have of washing themselves with alkaline water or bad soap. Amblyopia and myopia, so very prevalent among typographists, terminate the sketch drawn by the author of the diseases of this interesting class of artisans, with whom we are in daily contact, and whose intelligence and diligence we have constant reason to admire.—'L'Experimentale,' December, 1859, and 'British American Journal.'

ACUPRESSURE AND THE INTRA-UTERINE PESSARY.

Dr Bonnafont presented to the Academy several instruments used by Professor Simpson, of Edinburgh: 1, for the purpose of checking arterial hæmorrhage by acupressure; 2, to rectify uterine deviation.

From information received by M. Bonnafont during a recent visit to Edinburgh, it would appear that Mr Simpson has modified his original mode of applying acupressure, and now does not include in the parts pressed upon by the needle the entire thickness of the flap. The needle applied to the bleeding surface of the flap, in a direction opposite to that indicated in the original process, now comprises but a portion of the soft parts, and does not perforate the skin. It is withdrawn after forty-eight hours with the metallic wire attached.

With regard to Mr Simpson's intra-uterine pessary, M. Bonnafont stated that Mr Simpson has now reduced the rod to a length of fifteen or eighteen lines, and limits its use to cases of retroversion. From Mr Simpson himself, and other Edinburgh practitioners, M. Bonnafont was led to understand that this mode of treatment has invariably yielded most satisfactory results, without giving rise to any of the perils which it has been considered capable of inducing.

A practical point upon which Professor Simpson laid much stress in his conversations with M. Bonnafont on the subject, consists in the necessity of never removing the instrument after it has once been introduced; he has remarked that the organs suffer from frequent removal and reinsertion, a practice which also allows of the return of the womb to its improper situation during the intervals.

M. Bonnafont also remarks that Mr Simpson's precept, with regard to the mode of securing the instrument in its place, appears important. Mr Simpson uses no belt, but merely bends the hypogastric plate in such a manner as to accommodate it to the size and shape of the patient: thus the instrument adapts itself to the movements of the womb, and of the abdominal parietes; whereas a belt, securing the apparatus with too much solidity in one position, occasions, if not great pain, at least considerable discomfort to the wearer.

M. Dépaul could not agree with M. Bonnafont in considering Mr Simpson's instrument as either useful or innocuous. He persisted in thinking, grounding his opinion on the cases of Mr Simpson himself, and of others, that this method exposes the patients to very great peril, and rectifies the direction of the womb on the condition only of inducing peri-uterine phlogosis, by which the uterus becomes ultimately fixed in its new position.

With regard to acupressure, M. Velpeau remarked that numerous procedures had been proposed for the obliteration of arteries without ligature, and that all these methods had in succession been abandoned. The eminent Professor is inclined to think that acupressure will share the same fate; he tried it on two occasions, but in both serious inflammation set in, and compelled him to withdraw the needles. M. Foucher has also given the plan a trial at Hopital Necker, but he has not published the results of his cases, whence M. Velpeau infers they must have been unsatisfactory.

At the following meeting, M. Foucher, who had been stated by M. Velpeau to have applied Mr Simpson's procedure, forwarded a letter in which we remarked the following passage:

"Acupressure is an efficient hemostatic method, which will be found very useful under certain circumstances, such as ossification or induration and friability of the arterial walls. This system does not appear to offer greater protection from inflammation and suppuration than ligature; neither does it seem calculated to promote these unfavourable consequences, provided the needles are withdrawn after 24, 36, or 48 hours at the furthest, a period amply sufficient to secure the patient from a return of hæmorrhage. The application of this method presents, however, sometimes much difficulty, and as its advantages are not obvious, the usually adopted hemostatic procedures should not be discontinued."—'Journal of Practical Medicine and Surgery.'

FOOD FOR BABES, OR ARTIFICIAL HUMAN MILK,

AND THE MANNER OF PREPARING IT AND ADMINISTERING IT TO YOUNG CHILDREN.

This is the title of an admirable little duodecimo from the pen of Dr Cumming, of Williamstown, Mass.

He proposes a plan for supplying Artificial Human Milk to infants unable to procure from the maternal breasts nutriment of the proper quality and quantity. He has adopted this plan in his own household for a number of years with the most gratifying success. He claims that it produces a wonderful immunity from colic, pain in teething, and various disorders of the stomach and bowels; that it contributes materially to uniform growth, prosperity, vigour, and health, if it does not secure it; and that in many cases it will relieve almost instantly the distressing symptoms of wasting diarrhœa, &c. He states that in composition it closely resembles the natural secretion of healthy and vigorous mothers, and contains all the ingredients necessary for the proper growth and development of the child. This artificial human milk is to be obtained in two ways:

1st. By taking the upper third of cows' milk that has stood for four or five hours; this containing 50 per cent. more butter than the ordinary milk of the cow.

The second, and in warm weather the better way, is to take the milk from the latter half of that given by the cow, (containing 'strippings,') taking care that the cow be milked dry. In both instances, the milk is to be diluted with 1½ parts of soft water, and properly sweetened with loaf sugar. The animal from which the milk is to be taken must be from four to ten years of age, and free from disease of any kind, it being unimportant that she should give a large quantity of milk. Her calf should not be less than two weeks old; and when it becomes four or five months old, the cow is to be given up and another selected. The best feed for the cow is hay and salt and water, which will improve the quality of milk, though the quantity may be less than when other articles of food are employed.

Various dilutions are, of course, required for various ages.

Thus, for the first two weeks after the child's birth it is to be furnished with an artificial colostrum, which requires the use of the upper eighth instead of the upper third of the milk which has stood for four or five hours; or, the employment of the last tenth of the milk furnished by the cow.

A schedule is given, arranged to suit the wants of vigorous children of various ages.

Attention is to be paid to the physical condition of the child, as well as its age, in preparing the required dilution.

The milk should be prepared twice a day in warm weather, unless kept on ice.

The milk is to be administered by means of a bottle, with the neck occupied by an artificial nipple composed of a goose-quill rolled up in a strip of muslin; all of which are to be kept scrupulously clean.

The milk should be given at regular intervals, the child taking at each as much as it wants; and the child should be trained to pass six or eight hours at night without being fed.

The temperature of the milk when given should be about 100°; it should be taken slowly, and the flow from the bottle controlled by a proper arrangement of the quill and muslin.

Dr Cumming thinks this mode of feeding should be continued until the children obtain their full set of teeth, or to nearly the age of two years—or at least rely exclusively on it until sixteen teeth are fairly developed, when other food may be gradually commenced with.—'Medical and Surgical Reporter, and British American Journal.'

LEGAL INTELLIGENCE.

COURT OF QUEEN'S BENCH, Nov. 21.

(*Sittings in Banco, before* Lord Chief Justice Cockburn, *and* Justices Wightman, Hill, *and* Blackburn.)

STEELE (APPELLANT) *v.* HAMILTON (RESPONDENT).

This was a case stated by the stipendiary magistrate of Liverpool for the opinion of this Court, and it raised the question whether the facts set forth in the case were sufficient in law to warrant the conviction of the respondent, whom the magistrate had declined to convict, of an offence against the 40th section of the new Medical Act.

It appeared that the appellant, Arthur Brown Steele, hon. secretary to the Liverpool Medical Registration Society, had caused the respondent, John Hamilton, to be summoned before the magistrate upon an information which charged that he, on the 21st of February, 1860, wilfully and falsely pretended to be a surgeon, general practitioner, or apothecary, and used the name of surgeon, general practitioner, or apothecary, or some name, title, addition, or description, implying that he was registered under the Medical Act, or that he was recognised by law as a surgeon, practitioner in medicine, or apothecary, whereby he had become liable to a penalty of 20*l*. When the respondent appeared before the magistrate, it was proved that he had signed the following certificate:—

"MEDICAL CERTIFICATE.

"I hereby certify that I attended William Hayes, late of 110 Mill street, that died the 21st day of February; cause of death, enteritis; and that I have no reason to attribute his death to poison, violence, or criminal neglect.

"JOHN HAMILTON.
"Profession, Botanic Surgeon.
"Residence, 94 Mill street.

"Day of February 22nd, 1860."

It was also proved that over the door of the house where the respondent carried on his business was painted, in large, legible letters, "J. Hamilton, Surgeon;" and in very small characters underneath, "Boston, U. S.:" and upon a glass panel of the door itself was painted, "J. Hamilton, Anti-Registered Surgeon," The words "anti-registered" were considerably smaller than the words "J. Hamilton, Surgeon," and so as to be illegible, except upon close inspection. The magistrate dismissed the information, but, being required by the appellant to state a case, he submitted the following question to this Court,—namely, "Whether the evidence was sufficient in law to warrant a conviction under the 40th section of the Medical Act. If the Court are of opinion that the evidence was sufficient in law, then the magistrate prays the Court to make such order or conviction as the Court shall think fit."

Mr L. Temple, who appeared for the appellant, feared the case must be governed by the decision in the Court of Common Pleas, "Pedgrift *v.* Chevallier" (29 L. J., M. C., 225), unless it could be shown that the respondent was not in practice before the 1st of August, 1815. Nothing was stated on that subject in the case; but as the respondent, he believed, was only about forty years of age, he applied that the case might be sent back to be amended.

Mr Cook Evans (with whom was Mr Seymour), for the respondent, said the case had already been before the magistrates, both of whom had refused to convict, and he hoped the case would not be sent back. He should contend that the case was concluded by the decision in the Common Pleas, where it had been held that for a person merely to call himself a surgeon, without being duly registered, was no offence against the 40th section.

Mr Temple contended that the respondent had falsely pretended to be a surgeon by signing a medical certificate for burial. The 37th section of the Medical Act enacted that no certificate required by any Act of Parliment should be valid unless the person signing the same be registered under the Act.

Mr Evans said that the 37th section referred to cases where the certificate of a surgeon was required—for instance, in the case of an insane person whom it might be proposed to send to a lunatic asylum. But the certificate as to the cause of death might be given by any person who was present at the death.

Mr Justice Hill referred to the 25th section of the Registration Act (6th and 7th William IV., cap. 86), and said that it was so.

Mr Justice Blackburn thought that part of the case was disposed of.

Mr Temple proceeded to call attention to the case, in which it was found that the words "anti-registered" were written in very small letters, so as to be illegible except upon close inspection.

Mr Justice Wightman referred to the 40th section, and suggested that, to bring the case within it, it must be shown that the party falsely pretended to be a surgeon, &c., "implying that he is registered under the Act, or that he is recognised by law as a physician or surgeon," &c.

Lord Chief Justice Cockburn said there was nothing in the Act to prevent a person from merely practising as a surgeon without being registered. His Lordship thought that the decision of the magistrates should be affirmed, but, at the same time, he thought that a person who wrote "anti-registered" in very small letters was not entitled to costs.

The other Judges were of the same opinion.

Judgment affirmed, without costs.

DUMFRIES CIRCUIT COURT.

David Gibb, medical student, Glasgow, was charged, on Sept. 28th, before Lord Cowan, with the crimes of "falsehood and forgery, in so far as, on or about Tuesday, the 3rd July, 1860, at or near Rosehall, in the parish of Dumfries, the said David Gibb, being desirous of obtaining the appointment of assistant-surgeon to the Dumfries, Roxburg, and, Selkirkshire Militia, did wickedly and feloniously, at aforementioned place, write and fabricate, or cause to be written or fabricated, a simulated document purporting to be a diploma of competence from the Faculty of Physicians of Glasgow, and did utter and use such document, he well knowing it to be a forgery." The panel pleaded guilty of uttering and using such document.

Mr A. T. Boyle, prisoner's counsel, in extenuation, said that the panel, as student in the Andersonian University of Glasgow, bore the most irreproachable character. Mr Boyle produced certificates to that effect from Professors Bell, Moreton, and Penny, of the Andersonian University, Glasgow, and from Dr Watson, of the Royal Infirmary there. Dr Boyle said it had not been out of any sordid motives that his client had uttered this document. Mr Gibb had made every reparation in his power by repaying the small sums he had received as salary while performing the duties of assistant-surgeon.

Lord Cowan said that it was one of the most painful cases he had ever met. It was within his recollection when forgery was visited with the highest penalties of the Court. Luckily this case was not one such as the forgery of bank bills, but one which had been of little benefit to the panel. But, even looking at the present offence in its mildest form, he could not, sitting there to award impartial justice, visit it with a less penalty than twelve months' imprisonment, in order to show all that in this country no good could be attained by evil. He hoped that when the prisoner was restored to society this would prove a lesson to him.

WILLIAMS *v.* REV. C. LLOYD, OF CHALFONT ST GILES.—In this action, which was tried at the Chesham County Court on Monday, November 19, before J. Whigham, Esq., Judge, Mr Day appeared for plaintiff, and Mr Codd for defendant.—The plaintiff is a surgeon, and at the time the amount sued for was alleged to be contracted, practised at Chalfont St Giles, from whence he has removed. The amount sought to be recovered was 11*l.* 4s. for professional attendance on the Rev. C. Lloyd's family, and a kitchen-maid in his service, whom plaintiff had attended at the request of the defendant. It appeared that the point in dispute was whether the plaintiff was entitled to a charge for visits, for which 2s. 6d. each had been charged, though within half a mile distant from his own house, in addition to the charge for medicine, and a further charge on each account for professional attendance. The rev. gentleman was of opinion that he was not, and he had accordingly struck out the charge for the visits, and had paid into court, altogether, the sum of 8*l.* 10s. 6d., which he believed was as much as he was entitled to.—The plaintiff was examined, and at Mr Codd's request, after considerable discussion, produced his diploma, and also a copy of the Medical Register, to show that he was duly qualified to act in the capacity of a surgeon and apothecary: he, however, had omitted to bring his certificate.—Plaintiff stated that he attended defendant and the persons mentioned in the bill at his request; the charges were reasonable, and the same that he had charged for years.—Mr Codd, after cross-questioning the plaintiff, addressed his Honour on behalf of defendant. He said he did not wish to deprive plaintiff of a fair compensation for his services, but he considered he was not entitled to the three charges, viz., visits 2s. 6d. each, then a charge for medicine, and then afterwards professional attendance. Mr Codd contended that, in point of law, he (plaintiff) was not entitled to charge for visits and professional attendance, and he was of opinion that the amount paid into court was ample remuneration for his services.—A. B. Brickwell Esq., Surgeon, of Amersham, was then examined on behalf of defendant. He said—I have been in the habit of attending people at Chalfont St Giles; I charge for journeys; I have never seen a bill before in which visits, medicine, and medical attendance were charged; I do not charge for journeys in the town; the general rule is not to charge for journeys, but for professional attendance and medicine; the charges for medicine are about the usual charge.—The Rev. C. Lloyd, the defendant, then said—On the 12th January in the present year, the plaintiff commenced visiting my children; they were suffering from slight colds; there was nothing serious; considering that Mr Brickwell only charged 2s. 6d. for a journey from Amersham, which is 3½ miles, I thought plaintiff charged too much; I wished to pay the 20s. charged for professional attendance, but not for the amount charged for visits; Mr Williams offered to diminish the bill; I considered the sum paid into court quite sufficient. The defendant explained that in addition to attendance upon his own family, plaintiff attended several other persons, his parishioners, at his request; but thinking the charges exorbitant, he had deducted some of them.—Mr Day then addressed his Honour in behalf of his client. He deprecated the mode which had been adopted by defendant, which he described as a 'paring down flint' sort of proceeding. The first person sent for was the medical man, and they were the worst paid of any profession. Mr Brickwell had said that the charges were moderate, and for his part he thought medical men's charges should be regulated by what they had to do. He would certainly rather hear them talk than swallow their doses (laughter).—His Honour observed that the medical profession ought to be regarded with the kindest consideration by the entire community, as they performed their duties often at great inconvenience, and with the greatest possible care and attention. He did not know any profession that came up to it, except the clergy. He did not think in the present case either party could be blamed for niggardliness. His Honour decided that but two charges could be made, and gave a verdict for 1*l.* 7s. 6d., in addition to the amount paid into court, and costs.

Births, Marriages, and Deaths.

BIRTHS.

FOWLER.—November 24, at Bishopsgate street Without, the wife of Robert Fowler, M.D. Edin., of a son.

HORTON.—November 25, the wife of Charles Horton, M.D., of Bromsgrove, Worcestershire, of a daughter.

LAKIN.—November 8, at Kineton, the wife of Dr Lakin, of a son.

PEARCE.—November 20, at Bethnal-green road, the wife of Samuel Pearce, Esq., Medical Officer of Health, prematurely, of a son.

RANDALL.—November 26, at Portman street, Portman square, the wife of John Randall, M.D., of a daughter.

REED.—November 22, at Hazelwood-by-Thirsk, Banffshire, the wife of Daniel Reed, M.D., of a son.

SHONE.—November 22, at Harbury, Warwickshire, the wife of W. J. Shone, Esq., M.R.C.S., of a son.

MARRIAGES.

OGILVIE—PILCHER.—November 15, at All Saints Church, Blackheath, Charles Fred. Ogilvie, M.D., Bombay Army, youngest surviving son of the late John Ogilvie, Esq., M.R.C.S. Royal Navy, to Anne Emily Pilcher, third daughter of James Pilcher, Esq., of Bow, Middlesex.

TAYLER—BRISTOW.—November 21, at St George's, Hanover square, William Henry Tayler, Esq., M.R.C.S., son of Vice-Admiral Joseph Needham Tayler, C.B., of Brixton, to Mary Ann, widow of the late John Charles Bristow, Esq., of Esmere hill, Ullswater, Westmorcland.

DEATHS.

BREMNER.—November 23, at Huntley, N.B., Jas. Bremner, M.D. Univ. King's Coll. Aberd., L.R.C.S. Edin., Assistant-Surgeon 47th Regt. of Bengal Native Infantry, aged 25.

CLUTTON.—November 16, Thomas Clutton, Fellow of New College, Oxford, M.D., aged 56.

COLES.—November 20, at Weston-super-Mare, Somersetshire, James Coles, Fell. and M.R.C.S. Eng., L.S.A. Lond., late Sen. Surg. Hosp. Dep., Great Portland road, aged 57.

EAGER.—November 24, at Kilronan Glebe, Co. Roscommon, Matthew Wyatt Eager, M.R.C.S. Lond., late of Athenry, Co. Galway.

GRAHAM.—November 17, John George Graham, of Stockport, Cheshire, M.R.C.S. Eng., aged 29.

HALAHAN.—November 3, at Guernsey, Dr Halahan, Inspector-General of Hospitals, late Royal Artillery, aged 70.

MARTIN.—August 20, at Tangkoo, China, of dysentery, Charles Henry Martin, of H.M. Medical Staff, only son of C. N. Martin, of Harley House, King's road, Chelsea.

THOMSON.—November 25, at Exeter, William Thomson, M.D. Glasgow, L.R.C.S. Edin., aged 61.

YOUNG.—November 18, at Gressford cottage, near Wrexham, the infant son of Lake Young, Esq., M.R.C.S., aged 3 months.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations, were admitted Fellows of the College, at a meeting of the Court of Examiners, on the 29th ult.:—George William Fleetwood Bury, Whetstone, Middlesex—diploma of membership dated Dec. 12, 1856; Wm. Clapton, St Thomas's Hospital—March 20, 1857; Thomas B. Crosby, Finsbury place—May 21, 1852; William Lewis Dudley, M.D. St Andrew's, Bogota, New Granada, Hart street, Bloomsbury—Dec. 29, 1846; Walter Battershell Gill, M.D. Lond., Cambridge place, Regent's park—April 9, 1847; Eustace Smith, M.D. Lond., Leamington—Nov. 5, 1858; Thomas James Woodhouse, Wells street, Hackney—March 20, 1857. It may not, perhaps, be generally known that, by a recent regulation of the Council of the College, Graduates in Medicine of the Universities of London, Oxford, and Cambridge, are admitted to the Fellowship after having passed the professional examination in Surgery only.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, the 22nd ult.:—William Hayle, Slaithwaite, Yorkshire; Robert Iliffe, Coventry; James Savage, Burlington quay, Yorkshire; James Steele, Lancaster; John William, Dyffryn, Merionethshire. And on the 1st November, Frederick William Ricketts, Liverpool. The following gentlemen also on the same day passed their first examination:—Henry May, Birmingham; Richard Canning Tanner, Painswick, Gloucestershire.

OXFORD.—The Examiners appointed by the electors under Dr Radcliffe's will (Dr Acland, Dr Rolleston, and Professor Brodie) give notice, that they propose to begin an examination for a Travelling Fellowship on December 4, in the Medical Department of the University Museum. Those may be admitted as candidates who have taken a first class in the Natural Science School of Oxford, and who intend to qualify themselves to practise Medicine as Medical Graduates of the University. The successful candidate will receive 200*l.* a-year for three years, half that time being occupied in Medical study out of Great Britain.

THE ROYAL MEDICAL AND CHIRUGICAL SOCIETY.—The following gentlemen will be balloted for, as Fellows of this Society, on Tuesday evening, December 11, 1860. The ballot will be opened at half-past seven o'clock, and will close at half-past eight precisely:—Messrs. Richard Cross, Robert Cameron Galton, Herbert Chalmers Miles, and William Ogle.

WOOLWICH DISPENSARY.—The New Military Dispensary in course of erection at Woolwich, intended also to provide for the temporary reception of severe Hospital cases, pending their removal to the Infirmary about to be built on Kidbrooke Common, is now partially roofed in. The position is considered to be one of the most

ligible in and about the garrison, both for its elevation and its near proximity to the barrack, review, and practising grounds, in which accidents may occur requiring surgical aid. In order to procure pure air and ventilation, an additional space of ground beyond the building is ordered to be cleared. The residence of Rear-Admiral Duntze is about to be demolished for that purpose.

Appointments.—Mr Charles F. Keele, M.R.C.S., late of St Thomas's Hospital, has been elected House-Surgeon and Secretary to the Royal Portsmouth, Portsea, and Gosport Hospital. John J. Nason, M.B. Lond., has been appointed a Surgeon to the Stratford-on-Avon Infirmary.

Manchester Royal School of Medicine.—The award of scholarships and prizes for the session 1859-60 took place at the Royal Institution on Thursday afternoon, the 22nd ult., as follows:—*Prizes for Third-Year's Students.*—Scholarship, value 20*l.*: Mr John Cockcroft, Middleham, Yorkshire. First Prize, value 5*l.* 5*s.*: Mr Daniel John Leech, Stretford. Second Prize, value, 3*l.* 3*s.*: Mr W. H. Barlow, Manchester. *Prizes for Second-Year's Students.*—Scholarship, value 15*l.*: Mr Herbert Grove Lee, Thame, Oxfordshire. First prize, value 5*l.* 5*s.*: Mr James Yates, Oldham. Second prize, value 3*l.* 3*s.*: Mr F. R. Fairbank, Moss Side. Third prize, value 2*l.* 2*s.*: Mr James Allen, Pott Shrigley. Fourth prize, value 1*l.* 1*s.*: Mr E. H. Roe, Eccles. Certificate of merit: Mr J. W. Morris, Rochdale. *Prizes for First Year's Students.*—Scholarship, value 10*l.*: Mr J. W. Renshaw, Ashton-upon-Mersey. First prize, value 5*l.* 5*s.*: Mr E. Dawson, Manchester. Second prize, value 3*l.* 3*s.*: Mr S. Messenger Bradley, Manchester. Third prize, value 2*l.* 2*s.*: Mr F. W. Booth, Ashmond, Lees. Fourth prize, value 1*l.* 1*s.*: Mr Hugh Moss, Congleton. *Certificates of Merit.*—Mr J. D. Mann, Kendal; Mr John L. Rushton, Rainow, near Macclesfield; Mr Robert Platt, Cheetham hill; and Mr Morris.—*Certificates of Honour.*—Messrs Alfred Heap, S. A. Patrick, F. J. Roberts, Joshua Handley, Thomas H. Dickinson, Robert Platt, F. W. Booth, E. Kershaw, J. Whittham, D. Elias, W. J. Renshaw, H. Moss, R. W. Coles, E. Dawson, T. Wilson, W. Clarke, E. H. Roe, H. Cartmel, D. Meany, H. G. Lee, W. H. Hughes, A. F. S. Clarke, J. Yates, J. Hollingworth, B. C. Smart, J. W. Morris, F. R. Fairbank, J. Anderson, J. Welsh, J. L. Rushton, E. T. Newbold, G. Hunstone, W. Bird, J. Watson, J. D. Mann, J. Allen, J. Bott, N. M'Guire, J. Gregory, J. Gwither, P. Byrnes, W. H. Flint, S. Bradley, and G. Newton.

Testimonial to a Physician.—On the 23rd ult., a very handsome and valuable time-piece was presented to Dr Philip H. Williams, of Worcester, with a purse containing 125 sovereigns, as an acknowledgment, by the subscribers to the Dispensary in that city, of his services rendered to the Institution during the period of twelve years.

The Longevity of Paupers.—There are at present in the Ratcliff and Wapping Workhouses of the Stepney Union 69 inmates whose collective ages amount to 5538 years, giving an average of 80 years for each inmate, and 292 persons in the above-named Workhouses of the Stepney Union whose average ages are 70 years.

The Longevity of Quakers.—The following ages of some deceased members of the Society of Friends during the present year are taken from the obituary of the 'Friend,' a monthly journal, published by that body. They are as follows:—84, 84, 85, 85, 85, 86, 86, 87, 87, 88, 88, 89, 89, 89, 91, 91, 91, 91, 91, 91, 92, 92, 93, 93,—making a total of 2128 years, with an average for each life of rather more than 88½ years. Fifty lives in the same period give 4258 years, with an average of 85 per life. These facts entitle one class of men to a favourable comparison with the Peerage as regards longevity.

Dr Tommasi, a Neapolitan, the most distinguished physiologist in Italy, has departed from Naples to resume his duties as Professor of the University of Pavia. The Doctor, it seems, is unable to practise successfully on the body political of Southern Italy.

'La Espana Medica' informs us that Dr Alvarez, of Cadiz, has successfully treated a case of diabetes with large doses of sugar, alkalis, and gelatine. He completely cured his sick man in thirty-six days.

The Humane Society's Medal has been given to Mr William F. Harton, Medical Student, for saving Matilda Broadhead, who attempted suicide by jumping into the river Shannon, Banagher, King's County, on the 29th of August last.

French Medical Students, Session 1860-61.—The inscriptions for 1860-61 amount to 1196—viz., 1,132 for the Doctorate, and 64 for the lower grade of *Officier de Santé*. In 1859-60 the inscriptions amounted to 988.

M. Lukomski, who in 1858 reported the results he had arrived at in the treatment of syphilis by means of the inoculation of vaccine virus, announces that numerous further experiments made of this treatment in the clinique of the Faculty of Medicine at Moscow have fully confirmed his own observations. MM. Serres and Andral are to report thereon to the Academy of Sciences of France.

Singular Longevity of the British Peerage.—It is not a little remarkable that the members of the Peerage who have died since the year commenced, twenty-four in number, have exactly completed, on the average, the full measure of the allotted span of human life, the "three-score years and ten." They are as follows:—Viscount Arbuthnott, 82; Lord Londesborough, 54; Viscount Southwell, 83; Viscount Gormanston, 84; Lord Oranmore, 72; Bishop of Rochester, 84; Earl of Longford, 42; Baroness Stratheden, 63; Lord Fitzgerald, 60; Viscount Guillamore, 27; Baroness Wentworth, 67; Earl of Stratford, 82; Lord Heytesbury, 80; Archbishop of York, 71; Lord Sandys, 68; Lord Elphinstone, 53; Bishop of Worcester, 77; Earl of Lauderdale, 76; Earl of Cawdor, 70; Lord Ffrench, 74; Earl of Leven and Melville, 75; Duke of Richmond, 69; Earl Manvers, 82; Earl of Dundonald, 85. Total of united ages, 1680 years, which being divided by 24, gives exactly 70 years to each.

Death from Chloroform.—The 'Gazette des Hôpitaux,' referring to the case of death from chloroform related in the 'Cincinnati Observer,'—in which, by means of artificial respiration, the contractions of the heart were kept up for an hour and a quarter, and occasional spontaneous respiratory movements were obtained,—adds that another case of death has also lately occurred at Paris, the patient being a young man, aged 24, who was submitted to chloroform by M. Fano, in order to undergo an operation for in-growing nail. No particulars of this case have as yet been made known, beyond the fact that for some time after the cessation of the pulsations of the heart, the patient made, at several intervals, spontaneous inspirations and expirations.

Linnæus and Buffon were born in the same year, one in May, the other in September, 1707; but this identity of dates, the force of their genius, the grandeur of the services rendered by them to natural history, are the only real points of resemblance between them. Linnæus was born in a little village in Sweden, a country still warlike and barbarous; Buffon in the bosom of a noble and rich family, in the France of Louis XIV. Linnæus was compelled to become apprentice to an artisan, and sustained a long and painful struggle against adversity. If Buffon, needed a strong resolution, it was to resist the seductions of the soft and easy life which was opened to him by his rank and fortune. Both had received from Nature intellectual tendencies even more diverse than the circumstances in which they were placed. Linnæus, as patient and sagacious in the search after facts as he was ingenious in co-ordinating them; prudent rather than bold in his deductions; working long on minute details, and lost in them, as it were, to elevate himself at last with a more certain flight to the elevated regions of science; quick in forming hypotheses, but yet not deceiving himself by them; assigning with remarkable correctness to each idea its rank and value, as to each being its place; endowed with a perseverance which was never discouraged by obstacles nor fatigued by time; loving truth for itself, and finding that his shortest and simplest expression was also the most beautiful; always seeking that elegance proper to scientific writings, which results more from the concatenation of ideas than from a choice of words; lastly, without ever failing to be exact and concise, varying his style from the grave precision of a formula to that high poetry of which Genesis offers us the sublimest specimen. Buffon, sagacious and as ingenious as Linnæus, but in another order of ideas; disdaining technical details, neglecting the multiplying around him of observed facts, but seizing the most hidden consequences of those which he passed, and thus boldly elevating, on a fragile basis, a durable edifice, of which he alone and posterity could conceive the gigantic plan; refusing to imprison his fertile imagination in the narrow circle of methods, and yet, by a happy contradiction, creating one day a classification which Linnæus himself might envy; sometimes losing himself in unknown space, where he wandered without a guide, but yet rendering even his errors fruitful; impassioned with all that was beautiful, all that was grand; and if he completed nothing, daring to commence with all; to contemplate Nature in her entirety, and calling to his aid, to paint her worthily, the treasures of an eloquence that has never been surpassed. Linnæus was one of those rare types of perfection of the human intellect where synthesis and analysis meet in a just equilibrium, and enrich each other. Buffon was one of those men, powerful by their synthetic powers, who pass, with a bold step, the limits of their epoch, occupy themselves in new routes, and advance towards future ages, gaining all by their genius, as a conqueror by his sword.—G. St Hilaire.

Imperial Invalids.—The young Empress of Austria, who is suffering under pulmonary phthisis, had, as is well known, intended to winter in Madeira, and Queen Victoria had placed at the disposal of the Empress a vessel to convey herself and her suite of fifty persons to that island. It is feared, however, that this intention may be frustrated, a sudden attack of hæmorrhage from the lung having just occurred, which must be regarded as a serious evidence of the progress of the disease. The Empress of the French, who is sojourning in these islands, is also understood to have a medical object in her visit.

A Child Killed with Syrup of Poppies.—We have again to record the death of a child due to the incautious and deplorable use of this narcotic. The mother of Jane Davis, aged three months, had given her a dose of this preparation of opium to produce sleep, and the overdose administered caused death. The jury returned a verdict, "That the diseased died from the effects of the syrup of poppies, administered by the mother to procure sleep, and through misadventure." A verdict of manslaughter, with appropriate punishment, in one or two of these cases, might have the salutary effect of checking the pernicious practice of narcotizing children, which is so fertile a cause of excessive infantile mortality.

A Gallant Surgeon.—We record with high satisfaction the official report of the noble act of Mr Joseph Jee, of the 78th Regiment, whose self-devotion and heroic services during the mutiny in India have won for him the Victoria Cross and the decoration of the Order of the Bath. The former honour he received lately at the hands of the Queen, and his services are thus announced in the 'Gazette':—"Surgeon Joseph Jee, C.B.—For most conspicuous gallantry and important services, on the entry of the late Major-General Havelock's relieving force into Lucknow, on the 25th September, 1857, in having during action (when the 78th Highlanders, then in possession of the Char Bagh, captured two 9-pounders at the point of the bayonet), by great exertion and devoted exposure, attended to the large number of men wounded in the charge, whom he succeeded in getting removed on cots and the backs of their comrades, until he had collected the doolly bearers who had fled. Subsequently, on the same day, in endeavouring to reach the Residency with the wounded men, Surgeon Jee became besieged by an overwhelming force in the Mote Mehal, where he remained during the whole night and following morning, voluntarily and repeatedly exposing himself to a heavy fire in proceeding to dress the wounded men who fell while serving a 24-pounder in a most exposed situation. He eventually succeeded in taking many of the wounded, through a cross fire of ordnance and musketry, safely into the Residency, by the river-bank, although repeatedly warned not to make the perilous attempt."

A Medical Mayor.—We omitted from our list of Medical Mayors, last week, the name of Mr Cam, the Mayor of Hereford. This gentleman is one of the Surgeons of the Hereford General Infirmary, and is much respected by his professional brethren.

APPOINTMENTS FOR THE WEEK.

Wednesday, December 5.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

ROYAL INSTITUTION.—2 p.m.
EPIDEMIOLOGICAL SOCIETY.—8 p.m.
MEDICAL SOCIETY OF LONDON.—8½ p.m.

Tuesday, December 11.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

MEDICUS (King's Lynn).—1st. Yes.—2nd. Yes.
Dr H. PHILLIPS.—The circumstance does not affect the liability.
STUDENS.—Nekrobiosis is a phrase used by Virchow to denote that degeneration of the tissues that ends in their death.
SIGMA writes us a long letter on the title "Doctor," of which he justifies the use by Licentiates of a College of Physicians, on the ground of custom. He maintains that a Licentiate, being authorised to teach Medicine, is a *bond-fide* Doctor, and that, on the other hand, a pure University Doctor need not be a Physician. He suggests that the Universities and Colleges "should reciprocate rights and titles, and thus abolish the absurd distinctions which now make our Profession ridiculous in the eyes of lawyers and men of the world." On this point, we may observe that we have been all our life contending for a more simple and uniform status for the Profession, and have not yet despaired of seeing our hopes realised.
H. S.—It has not yet been received.
CHIRURGUS (Liverpool).—The case is one of great interest, but is not given in sufficient detail. We shall be happy to comply with your request.
AN IRISH SUBSCRIBER.—We have already noticed the case of the late Dr Wall. He was most shamefully used, and his memory deserves to be held in respect by his professional brethren. We hope that a subscription will be raised, sufficiently large to provide comfortably for his bereaved family.
ERINENSIS.—1st. Certainly.—2nd. We adverted to the dispute at the time of its occurrence; but we intend to resume the subject in connection with the general question of the operation of the Medical Act.
A LICENTIATE.—1st. There can be no doubt now that you are free to use the title.—2nd. The examination at St Andrew's embraces all the subjects connected with the study of Medicine: it is chiefly written, but the fact of a candidate having passed the examination at the Edinburgh College of Physicians would probably have some weight with the Professors. It would be prudent, however, for a candidate to study the subjects for a few weeks before presenting himself for examination.
AN OLD SUBSCRIBER.—The Coroner was wrong; but the blot is not a blot until it is hit.
Mr BURTON is thanked.
Mr J. SMITH.—Received, and shall be noticed.
Dr GRAILY HEWITT.—Received.
Mr COLEMAN.—Received.

(The following note has been forwarded to us: it behoves the Dr Jordan for whom Mr Churchill recently published certain works on 'Diseases of the Skin,' to deny the connection implied in this note:)

To the Editor of the Medical Circular.

SIR,—Jordan, the Skin Doctor, is son to a man who advertised a book entitled the 'Silent Friend,' from 19 Berners street, Oxford street. This book has lately reappeared in the name of Dr Jordan, 29 George street, Hanover square.

Dr Buchan's Pills and Ointment, so much puffed at the present time, belong to the same people, who send their advertisements of nostrums, and 'Essay on Skin Diseases,' both from the head-quarters, at 22 Newman street. I am, Sir, &c.,

INVESTIGATOR.

R. W.'s communication on the Oxford Appointment shall appear next week.
Mr WILSON.—Note received, and shall be attended to.
CHIRURGUS (Cheltenham).—Unfortunately, there is no redress.
M.D.—1st. Yes.—2nd. Yes.

National Assurance and

INVESTMENT ASSOCIATION,
5 PALL MALL EAST LONDON.

Empowered by Special Act of Parliament, 17 Vic., cap. 43.

ESTABLISHED A.D. 1844.

Assurances may be effected from £50 to £10,000 on a Single Life.
Credit for half the amount of the first five Annual Premiums.

PULVERMACHER'S PATENT

GALVANIC RHEUMATIC CHAIN BANDS.

Unequalled as are the effects of the Chain-Bands in all kinds of Rheumatic Pains, Gout, Neuralgia, Indigestion, Epilepsy, and Female Complaints, still more extraordinary is the relief they afford in Sciatica, Lumbago, Head, Ear, and Tooth-ache, Bronchitis, Urinary Disorders, and all those Maladies attendant on Debility and Loss of Nervous Functional Force, &c. Persons interested in this Invention can convince themselves of the efficiency and certainty of the curative power of the Chain-Bands, by perusing the Book,

PULVERMACHER'S MEDICO-GALVANIC IMPROVED SYSTEM,

containing extracts from the learned Works of Physicians, Physiologists, and Philosophers, marked with the pages from whence they are taken; numerous private Testimonials of a most interesting character, with Reports of wonderful Cures from the Hospitals of England, France, Germany, and America.

The Invention is adopted by the Académie de Médecine, Paris; the Royal College of Physicians, London; and by the Imperial Faculty of Vienna. It is also distinguished by the support of Sir C. Locock, Bart., Physician to her Majesty the Queen; Professor Oppolzer, Physician to the Emperor of Austria; by Dr Rayer, Physician to Napoleon III; and others of celebrity; and was rewarded at the Great Exhibition of all Nations in 1851.

Chain-Bands, 5s., 10s. 6d., 15s., 18s., according to power,

Messrs PULVERMACHER and Co., 73 Oxford street.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM,

32 SOHO SQUARE, LONDON, W.
October 22nd, 1860.

66 QUEEN STREET,
LONDON, 23rd August, 1860.

Messrs R. WORTHERSPOON and Co.,
46 Dunlop street, Glasgow.

DEAR SIRS,

I have, as requested to-day, visited the Royal Laundry, with reference to the Advertisement of the Nottingham Firm, who state that their Starch has been used for many years in the Royal Laundry, and have been assured by Mr Thompson, the Superintendent, that none but yourselves have any right to state that they supply Starch to her Majesty's Laundry, as no other Starch is there used, nor has been used for some years, but the Glenfield Patent Starch.

I have been further assured that your Starch continues to give complete satisfaction, and that though trial has been made of samples of various Starches, none of these have been found nearly equal in quality to the Glenfield.

I am, dear Sirs,

Your obedient Servant,

WM. BLACK.

Medical Practitioners Sup-

plied with ASSISTANTS, gratis, by MAIR and SONS, 34 Bedford street, Strand, who also DISPOSE of PRACTICES on moderate terms.

THE PARASITICAL DISEASES OF THE HEAD AND FACE.

By GEORGE ROSS, M.D., &c.,

Author of the 'Constitutional Relations of Diseases of the Skin.'

No. III.

SCALL HEAD,—PORRIGO FAVOSA.

(Continued from page 373.)

Contagiousness.—Much difference of opinion has also prevailed with respect to the contagiousness of scall head; but that doubt should be now dispelled. Scall head *is* contagious, but not in so high a degree as some persons suppose. The fact of its contagiousness has been proved by Remak and Bennett. The latter gentleman writes:

"Dr Remak, of Berlin, communicated the disease to his own arm in the following way:—He fastened portions of the crust upon the unbroken skin, by means of plaster. In fourteen days, a red spot covered with epidermis appeared; and in a few days more, a dry yellow favus scab formed itself upon the spot, which, examined microscopically, presented the mycodermatous vegetations characteristic of favus. Mentioning this fact to my polyclinical class, at the Royal Dispensary, in the summer of 1845, one of the gentlemen in attendance volunteered to permit his arm to be inoculated. A boy called John Baugh, æt. eight, labouring under the disease, was at the time the subject of lecture, and a portion of the crust taken directly from this boy's head was rubbed upon Mr M.'s arm, so as to produce erythematous redness, and to raise the epidermis. Portions of the crust were then fastened on by strips of adhesive plaster. The results were regularly examined at the meeting of the class every Tuesday and Friday. The friction produced considerable soreness, and in a few places superficial suppuration. Three weeks, however, elapsed, and there was no appearance of favus. At this time there still remained on the arm a superficial open sore about the size of a pea, and Mr M. suggested that a portion of the crust should be fastened directly on the sore. This was done, and the whole covered by a cuticular piece of adhesive plaster about the size of a crown-piece. In a few days the skin surrounding the inoculated part appeared red, indurated, and covered with epidermic scales. In ten days, there were first perceived upon it minute bright yellow-coloured spots, which, on examination with the lens, were at once recognised to be spots of favus. On examination with the microscope, they were found to be composed of a minute granular matter, in which a few of the cryptogamic jointed tubes could be perceived. In three days more, the yellow spots assumed a distinct cupped shape, perforated by a hair; and in addition to tubes, numerous sporules could be detected. The arm was shown to Dr Alison; and all who witnessed the experiment being satisfied of its success, I advised Mr M. to destroy each favus spot with nitrate of silver. With a view of making some further observations, however, he retained them for some time. The capsules were then squeezed out, and have not since returned. Mr M. had light hair, blue eyes, a white and very delicate skin. There is every reason to believe that the strips of plaster employed in the first attempt shifted their position, and that the crust was only properly retained by the circular piece of plaster employed in the second experiment.

"That the disease is therefore inoculable, and capable of being communicated by contagion, there can be no doubt; a result which accords with the observations of most Practitioners, and with numerous recorded facts. It must also be evident that it does not readily spread to healthy persons, and that there must be either a predisposition to its existence, or that the peculiar matter of favus must be kept a long time in contact with the skin previously in a morbid condition."

It is therefore necessary for the conveyance of the disease by contact, that the recipient should be in a condition predisposed to receive it. A fungus will grow only on a soil suited to its nature, and unless it meet with that no result takes place. The exudation in favus is of that subacid fermentative character which is the best adapted for the development of mucedinous growths.

Constitutional State.—It has been stated by Mr Erichsen, and assented to by Professor Bennett, that the favus exudation is very similar to the exudation in tubercle; and he calls favus "a tuberculous disease of the skin." With this opinion I quite agree. It is an important doctrine, as it opens up grave questions with respect to the constitutional origin of favus. The difficulty experienced in inoculating favus proves that a certain pre-existent condition of the system is necessary to success. this condition is the scrofulous taint. This view is corroborated by the nature of the exudation itself, as already pointed out. It is not necessary that this taint should be developed in any appreciable manner, as in swelled glands, ulceration, or mesenteric disease: it may exist in a latent and inactive form; but the constitutional cachexia must be sufficiently expressed, that, under given circumstances, it shall afford the peculiar sub-vitalised exudation that is suitable for the germination of the mycoderm.

As the disease continues, however, the constitution becomes more deeply affected, and scrofula in its most aggravated form is the ultimate result. The injury that the constitution suffers from a protracted continuance of the disease is irreparable, and hard glandular swellings, contracted chest, stunted growth, and idiocy characterise its victims.

External Causes.—Anything that deteriorates the general health may create a predisposition to Scall Head. It is, however, a disease that is observed chiefly among the poor, and especially among the dirty and ill-fed poor. It is, comparatively, a rare disease; I have never, indeed, seen a case of it except among the neglected children of the lowest classes of the community. Dirt, then, is its most common attendant, if not its most frequent cause. Impure air, and a general deficiency of ventilation in the homes of the poor, conjoined with insufficient and innutritious diet, engender the liability to this affection by impoverishing the blood and preventing its due oxygenation. The wretched wanderers in our streets, whose moral wants are now provided for by the institution of ragged schools, are the especial subjects of scall head.

Running or moist scall, which is a different disease, and often vulgarly called "scall head," is not thus confined to the lowest classes, but may present itself among the children of persons of cleanly habits and good means, and where there is no lack of good food, warm clothing, or careful attendance. The same remark applies to ringworm. Indeed, I have seen more ringworm among respectable families than I have among the dirty and abject. I should say that ringworm is the pest of decent and well-cared-for children, whilst scall head is the nuisance of the miserable. In all cases of ringworm, I have noticed that the health of the child has always been below par at the time of the attack; that it has been slightly feverish, irritable, disordered in its bowels, and paler than usual in its complexion: in short, there has been *malaise*, though not sufficiently marked to be called sickness. It will be generally found that a child attacked with ringworm has been attending a school where other children have been suffering from the same disease; and I have no doubt that the close and unwholesome atmosphere of most children's schools induces the disease by impairing the health. Bad ventilation, confinement, and want of exercise, are the most frequent subordinate causes of ringworm; whilst dirt and privation are most commonly antecedent to scall head.

RUNNING SCALL,—CRUSTA LACTEA, ECZEMA IMPETIGINODES.

Among the many technical designations that have been given to this disease, I have selected those which are the most significant and comprehensive. This affection, indeed, simulates a variety of—so-called—distinct cutaneous diseases, and affords one of the best examples we could desire to prove that many of the numerous varieties of these affections are associated together by intimate constitutional relations. Running scall is, however, altogether a distinct disease from favus, or dry scall. It is best seen on the face, where it is noticed as a crop of minute vesicles seated on an inflamed surface. When these break, a discharge, which is trifling in mild cases, but copious and irritating in severe ones, flows from the cutis. The irritation is even so great, that I have noticed a patch no larger than the top of the thumb to cause inflammation of the adjacent submaxillary or cervical glands. The vesicles may become confluent, and spread over the skin of the face and head. When this condition ensues, the scalp is swollen and inflamed, and pours out an abundant viscous secretion. As the inflammation increases, the discharge becomes thicker, pustules form, and a greenish scab mats together the hairs, and covers the head and face as with a mask. In this aggravated form we have the disease called Eczema Impetiginodes.

A singular appearance of the hair has been noticed in this disease. When the scabs have dried in some degree, and have separated, each encloses a tuft of hair, which is collected into a pencil, and glistens with the discharge. The hairs shine like asbestos, from which one of its names has been derived.

This disease is accompanied with intolerable burning and itching, and worries the little patient night and day. At night, however, when the body is heated, the inconvenience is most felt; the child becomes restless and fretful, and sleeps badly. It may attack all parts of the body; but it is most usual on the ears and sides of the face, and flexures of the joints. The part attacked is always more or less swollen at the onset; and if the disease persist, the skin becomes thickened, and the discharge abates, or may altogether cease. At this period a scurfy condition of the skin may remain, which has received various names, according to the particular aspect which it may present; as, for example, pityriasis capitis, and psoriasis infantilis.

Running scall is often observed in children at the breast; and in the early months of the first dentition it is associated with red-gum and other forms of lichen. Unless cured early, it becomes very obstinate, and may continue, with periods of remission, until puberty. Children with a delicate skin are very liable to it, and so also those of a strumous diathesis. Where this diathesis exists, an innutritious quality of food, and irritating matters in the primæ viæ, are very apt to call the disease into activity.

DANDRIFF,—*a.* PITYRIASIS CAPITIS.

This disease is characterised by minute white micaceous scales, which are attended with itching and heat, and sometimes cover the entire head. They may be brushed off in large quantities. Like all other cutaneous diseases, its first appearance is usually harbingered by a little feverishness, and the scalp is slightly

reddened; but this coloration disappears. It is usually most abundant at the top and sides of the head; it is commonly noticed also at the margin of the hair, about the face and forehead. It confines its attacks usually to the young and the aged. By frequent scratching, pustules sometimes form; and if the disease be long continued, baldness results. In young children, however, this is not irremediable. This disease often lays the foundation of other more serious and troublesome affections of the skin. In bald-headed persons, a red patch covered with small scales is sometimes noticed on the vertex: this is pityriasis. A similar patch is occasionally observed on the face and aronnd the mouth, where it is very troublesome.

b. Psoriasis Capitis differs from pityriasis in the greater thickness and size of the scales; and though they are also white, they have not the glistening look of the former disease. They are also more fissured. Psoriasis capitis is rarely seen in the absence of psoriasis on the body. When, however, it exists alone, it stops short at the roots of the hair, covering the head as with a scabby cap.

CLINICAL LECTURES.

ON EXOPHTHALMIC GOITRE.

NEW FACTS TOWARDS A HISTORY OF THIS DISEASE.

Delivered at the Hôtel Dieu,

By M. TROUSSEAU.

There are diseases that spring up all at once; and attention is directed to them by the sudden appearance of several cases. According to Dr Stokes, Dr Graves of Dublin, in 1835, delivered some clinical lectures on an affection characterised at once by goître, exophthalmia, and disorders of the heart. The fact is that, in the book which he published in 1843, Dr Graves has related cases in detail, described by the hand of a master, the reading of which leads us to believe that this eminent clinical teacher was unacquainted with the labours and researches on this subject published in other countries. It is probable that Graves in Ireland, and Basedon in Germany, gave, at the same time and without any intercommunication, an exposition of the singular phenomena that distinguish the pathological triade of which I am about to speak.

In 1833 I had under my care a lady affected with goître. By my directions, she took iodine; and she had, in consequence, an iodic fever. I recollected afterwards that she suffered from palpitation of the heart, and that her eyes had become exceedingly prominent. But seeing no connection between these facts, I looked only at the disease. I do not, therefore, lay any claim to priority; but I say that were every old Practitioner to search the stores laid up in his memory, he would probably find similar reminiscences.

In England, Germany and France, Graves, Stokes, Basedon, Charcot, Gros, Aran, and several other observers, have made us acquainted with several cases of exophthalmic goître. For myself, during the last five or six years that attention has been given to this disease, I have seen in all nine cases. At this moment, in the Salle St Bernard, No. 27, we have a case of exophthalmos; and in No. 34 of the same ward we have a woman with exophthalmic goître. To these I shall presently return; but first I wish to speak to you of two patients under the care of Dr Labarraque. The first is a lad, fourteen and a half years of age, whose case may be thus shortly stated: He is slightly lymphatic; had hooping-cough when six or seven years of age, and typhus fever, not severe, when nine. When sent to school at twelve, he shared in all the games and exercises of persons of his age, and went through his gymnastic exercises, like his comrades, without suffering any degree of oppression. Yet, when taken by his family to the sea-side for the purpose of bathing, he could not bear immersion but for two or three seconds, for his vision became disturbed—his sight so short, and myopia became so marked, that in the course of a few weeks he had to make use of No. 9 lunettes. Before the vacation of 1860, the neck had begun to enlarge, and the general health was less satisfactory; beyond which there was nothing deserving observation. He now went to Tourville; but sea-bathing became impossible, for he suffered a violent attack of oppression, which, however, quickly yielded to the use of sinapisms. Dr Lebâtard, who happened to be there, was consulted on account of the enlargement of the neck, and recommended the use of iodine. Under this treatment, which was strictly followed, the disease got worse. Towards the end of the vacation nothing more was done, and he came back to Paris. His return to school, on the 10th of October, was considered as compatible with this state of health: but this state of things was soon to undergo a sudden modification. He changed, became pale and oppressed, and Dr Blache was called in consultation with M. Labarraque. Rest was enjoined, and revulsives were applied to the extremities; but suffocation made frightful progress, and one night, when Blache, Labarraque, and myself arrived, we found him with his eyes livid and projecting, and seemingly in the last agony. Our first thought was to open the trachea, and M. Dumarquay was desired to be in readiness at a moment's notice. We tried, however, to temporise. We had recourse to venesection. We applied ice to the throat, and gave digitalis in large doses. The very same night he slept nine hours. On awaking, he was seized with another paroxysm of suffocation. Bags of ice, as used by M. Aran, were applied to the anterior region of the neck, and all went on well. M. Dumarquay's aid was not required, and, at the end of a week, this young man's resurrection was complete. Yesterday, Nov. 9, his father brought him on foot to my house, though living at a distance of nearly four kilometres. I have not seen him; but I know that his eyesight is improved, that the goître has nearly disappeared, and that the palpitation of the heart has ceased.

The second case seen by M. Labarraque is as follows:—In 1855, at one of the dispensaries, he encountered a woman with a large neck, prominent eyes, and palpitation of the heart. He twice practised venesection—gave digitalis in large doses, and repeated purgatives. This woman got well. She was forty-six years of age. Now I must tell you that exophthalmic goître is rare at that age, and that it is habitually seen at an early period of life; under thirty years, for instance. Struck with the phenomena he had witnessed, M. Labarraque kept the case in mind, and obtained the following history:—This woman, a worker in lace, experienced, in 1849, extraordinary alarm, and immediately became subject to palpitation of the heart. When six months had thus passed, the neck began to enlarge, and the eyes became prominent. Hitherto she had been always able to work in the evening, and possessed an excellent myopic sight; but now she perceived muscæ volitantes, and large black specks floated before her eyes. It was under these circumstances that amenorrhœa occurred, with intense diarrhœa and furious appetite. This last symptom has been carefully noted in a great number of cases, and the boy of whom we have just spoken had eaten immoderately on the eve of the day on which an attack of suffocation so narrowly endangered his life. Although this patient devoured a prodigious quantity of aliment, and, among other items, a loaf of 4lb weight daily, she became excessively emaciated, and, after four months of total suppression of the menses, she became pregnant.

You know it has been said that fecundation takes place only at the menstrual period. Well, the preceding example would, in case of need, be a proof of the contrary; for conception took place, to all appearance, in the absence of ovulation. Persons of the Jewish persuasion—and when a religion is persecuted, its observers are more numerous than at any other period—conform religiously to an article of the Jewish law which prohibits sexual intercourse during the catamenial period. The husband cannot come near his wife for a week after, nor until she has taken a bath. Yet Israelitish families in general can reckon a great number of children.

M. Labarraque's patient, then, had intense diarrhœa, and an appetite notwithstanding, out of all proportions. In the ball of each eye she experienced such throbbings, that every instant she raised her hands to her eyes, which seemed as if going to fall out. This phenomenon was identically reproduced in the two phases of the disease, in 1849 and 1855. Her complexion, which was before highly coloured, became pale. Synchronous with the affections which she experienced on the part of the eye, the heart, and the neck, she complained of palpitation in the epigastrium—a symptom observed in other patents also. During her pregnancy, the hypertrophy of the thyroid gland disappeared—a circumstance which M. Charcot noted in the case he has related. After parturition, this patient's health returned, in spite of well-marked nervous susceptibility. Subsequently relapse showed itself by diarrhœa, hunger, &c. &c.; and it was then (1855) that she applied at the dispensary, and came under M. Labarraque's care.—Sleeplessness, a point on which some authors insist, was in this case painful and obstinate, and contributed in no small degree to render this patient irritable and nervous. Her handwriting became so altered, that when, on her daughter's marriage, she signed the contract, her signature was nothing but an unintelligible scrawl. The pulse has since continued to beat with frequency, and is still 108. There is also present a certain degree of oppression, goître, and exophthalmia; and the carotid arteries also are seen beating with a certain degree of impetus: but appearances are all good, and not far from the normal state.

(To be continued.)

ON PALSY SUCCEEDING TO NON-DIPHTHERIC ANGINÆ.

(From the 'Gazette des Hôpitaux.')

Since the question of diphtheric palsy has, by the publication of the admirable work of M. Maingault, been brought before learned societies and the Medical press, numerous cases, reproduced for the most part in our columns, have appeared, confirming in almost every point the propositions laid down by our distinguished *confrère*. But as cases have multiplied in the same degree that the attention of physicians has been directed to this subject, new problems have not failed to present themselves with the new facts that have been collected. It is thus, for example, that palsy of the palato-pharyngeal regions, which at first might have been supposed to be dependant

exclusively on diphtheric anginæ, (having been observed in different kinds of anginæ, and even as a result of simply inflammatory anginæ, of which M. Maingault has himself related examples,) it naturally occurs to us to ask, if this palsy be really something special and implying the notion of specific infection, or if, indeed, it is not simply a phenomenon common to many other diseases, and destitute of any specific character. This interesting pathological question has just been brought before the Medical Society of the Hospitals by a communication from M. Sée, and before the Medical Society of the Haut-Rhin by one from M. Marquez. We shall shortly give an exposition of the views contained in M. Sée's production, and of the discussion to which it gave rise; but for the present we shall confine ourselves to a succinct exposition of M. Marquez's cases, taken from the 'Gazette Médicale' of Strasbourg.

In May, 1859, A. V——, a young woman seventeen years of age, was taken with fever, headache, and nausea, preceded for a day or two by uneasiness, lassitude, and want of appetite. These general symptoms were accompanied by an angina, attended with increasing difficulty of deglutition, pain extending from the fauces to the interior of the ear, and, in a word, by inflammation of the entire throat and isthmus faucium. On the right side there existed a narrow gangrenous streak on the anterior face of the anterior pillar, and stretching over the velum palati as far as the uvula—a state of these parts which a characteristic odour did not fail to betray. At first an emetic, gargles, succinate of ammonia, and then quinine, were employed; and the parts were several times touched with nitrate of silver. This affection, which at first caused some anxiety, now rapidly advanced towards a cure. Nevertheless, the inertness of the movements of the velum palati, the *nasonnement* and dysphagia still persisted for some time, but varied in intensity, and subsided without any special treatment beyond dietetic regimen.

A girl, seven years of age, slightly lymphatic, and subject to affections of the throat, experienced, on the evening of the 8th of March last, uneasiness and slight want of appetite, to which, on the 9th and 10, succeeded more serious symptoms. These were shivering, headache, depression, frequent moaning, vomiting, coryza, slight cough, fever, increased thirst, and difficult deglutition, accompanied with acute pains that extended as far as the left ear; stiffness of the neck, and painful tumefaction under the left angle of the maxilla. These symptoms had been preceded by more than one attack of epistaxis. The throat is now seen to be inflamed; the pillars, velum palati, uvula, a part of the arch of the palate, the pharynx, and the right tonsil are moderately inflamed; but the inflammation is chiefly centred in the left tonsil, which is enormously swollen. Here the inflammation made rapid progress, and soon acquired in this tonsil such severity, that by the evening of the 10th the gland had become gangrenous, on the apex and anterior part of which there is a soft, dark-coloured, irregular eschar: the breath is fœtid, the pulse weak; and there is still stiffness of the neck, with difficult deglutition and pain at the angle of the maxilla. The treatment consisted in the application of leeches to the sub-maxillary swelling, embrocations with the *baume tranquille*, cataplasms, emollient gargles and fumigations, laxatives, diluents, chlorate of potassa, and, on the 10th and 11th, cauterizing with nitrate of silver. From the 12th to the 15th, tincture of myrrh was applied to the wound left by the separation of the eschar, and gargles containing the same preparation were used. From the 12th to the 16th there was gradual amendment; convalescence now became established, and the little patient recovered her cheerfulness and appetite. Yet deglutition, without being painful, was still more or less difficult. Lastly, when, towards the end of the month, this girl was about to return to school, it was noticed that her eyesight was affected—that there was amblyopia with presbytia. She complained at the same time of sub-orbital pains, which were irregular and of no great severity: she is pale, and her appearance chlorotic; eats little; her digestion is bad, and her strength, which was returning, now decays. The state of the mouth is seen on inspection to be natural, with the exception of slight enlargement of the tonsils. The urine, which was frequently examined, was found loaded with mucus, but contained neither albumen nor glucose. Exercise in the open air, saline baths, pepsine, iron, bitters, a strengthening regimen, and small blisters on account of the sub-orbital pains, were prescribed. On the 18th, Professor Stœber ascertained with the ophthalmoscope that neither in the interior of the eye nor in the membranes had any alteration occurred; and M. Marquez, by his advice, directed frictions with tincture of nux vomica to be applied to the temples and eyebrows, and, in case of failure, to have recourse to strychnine. When, after some days, the endermic use of nux vomica led to no appreciable result, two or three drops of a solution of sulphate of strychnine, in the proportion of 1 to 100, were each morning applied to the oculo-palpebral mucous membrane. This manner of using strychnine was soon followed by satisfactory results; the sight gradually improved, and had become distinct enough, but feeble, in the early part of May.

We shall dispense with any detailed account of the other cases, the chief points of which we shall only notice. The third case is that of a boy of eleven years, in whom palsy of the third pair occurred some days after simple angina. The palsy yielded, after lengthened treatment, to the use of hypodermic injections of a solution of sulphate of strychnine. In a fourth case, the patient, a girl of fourteen years, after suffering from a simple phlegmonous angina, sufficiently serious, however, to require very constant attention for ten or twelve days, became affected, after a short interval of convalescence, with palsy of the velum palati, complicated with diplopia. These symptoms disappeared under the use of strychnine and a strengthening regimen. No doubt, some degree of reserve must be used in regard to one of these cases, where the connection between the angina and the consecutive ocular palsy does not seem to us sufficiently established; but if we pass by this case as doubtful, three still remain to be added to those already published, constituting a considerable contingent of cases where palsy has succeeded to anginæ that were not diphtheric, and of which account must be taken: and this we shall do when we again return to this subject.

THE SPIRIT OF THE PERIODICALS.

The 'Dublin Quarterly Journal' contains some interesting articles, opening with an elaborate one by Mr Butcher, on *Operative Surgery*. His subject is *Amputation at the Knee-joint—at the Knee*—and *Excision of the Knee-joint*,—the respective advantages and disadvantages of which he compares. We quote the following remarks:

"The fatality attendant upon amputation of the thigh for years back has awakened a spirit of emulation amongst practical surgeons towards perfecting a better method. The circular, the oval, the various modifications of flap, have each been in vogue, vaunted, and praised, according to the ability and power of the originator, special methods becoming attractive, and adhered to for a time, in proportion to the mental capacity and operative dexterity of the surgeon,—the very abandonment of considerately weighed opinion going far to establish the truth, in which all agree, that amputation of the thigh is perilous in the extreme, stern hospital experience registering the fact, of how long and weary is sometimes the convalescence, the healing of the stump, and how often, too, the completion of the latter the source of much misery and pain. To many of those dangers consequent upon division of the compact tissue of the bone, pathology has pointed, and by the untiring investigations of Cruveilhier and others, they have been elicited and brought to light. Every museum affords abundant evidence, by irregularly-shaped exfoliations, how readily the compact structure of the bone perishes after the application of the saw, its periosteum being cut through and ruffled on the outside, sometimes even rudely, and its delicate vascular lining membrane in all instances lacerated and torn within. To no bone in the body do these observations apply with greater force than to the thigh-bone: its compact tissue is thicker, more dense than any other; and, above all, its medullary canal and lining membrane are more developed and extensive. Is it to be wondered at, then, that inflammation aroused in this vascular network should often terminate in suppurative crisis; nay more, in phlebitic complications and death? Professor Syme goes so far as to say, 'I believe the thigh-bone would be more fruitful of such exfoliation, if amputation through it were not so fatal;' and then he pronounces the fatality in these words: 'The average frequency of deaths is not less than from 50 to 70 per cent., while it cannot be denied that many of the survivors suffer from uneasiness connected with protrusion of the bone.' In a paper published by this surgeon in the 'Edinburgh Monthly Journal,' May, 1845, he considers these several points in relation to the fatality of amputation of the thigh, and concludes that the point 'radically wrong in the principle of the operation is dividing the thigh-bone through its shaft, instead of the condyles or trochanters.' The spirit of conservative surgery is abroad throughout the land; and to its powerful influence must be ascribed the restitution of those several operations about the knee, and in reference to which I wish to speak,—amputation at the *knee-joint*—amputation at the *knee*—excision of the *knee-joint*.

"*Amputation at the knee-joint*, though bearing its date years and years ago, was performed by Hoin, and with good results, so far back as 1764, and after him by several Continental surgeons, with varying success. Velpeau, in particular, has distinguished himself in reference to it, having frequently performed it with success. In America, too, the operation has found great favour: in an interesting paper by Dr Markoe of New York, published in the 'New York Journal of Medicine,' we learn that he has advocated this operation in preference to amputation of the thigh since 1841. He writes, that in this operation the bone is uninjured, while on the other (the operation through the shaft) it is divided with a degree of violence, the effects of which are not always appreciated. 'The effects of this violence both upon the bone and its envelopes, and of the exposure of the cavity of the medullary membrane to the action of air and pus, are seen in several of the accidents which occur after amputation, some of which are merely of sufficient gravity to annoy the patient and prolong the period of his cure, while others are of such danger and severity as materially to endanger life.' The exfoliation of the injured bone and the formation of tubular sequestra, the Author regards as due to the division of the nutritious arteries of the bone either by the saw or the catlin: the supply of blood to the medullary membrane, thus cut off, is too slowly supplied by anastomosis, and the bone dies. For the purpose of ascertaining the usual point of entrance of the nutritious artery into the bone, Dr Markoe examined 45 femora: in 23, the foramen was placed at about the junction of the middle and upper third; and in 22, at or near the centre of the bone: in several it was double. Dr Markoe remarks, phlebitis, 'another destructive consequence of such violence, is of much rarer occurrence in the well-regulated hospitals of the United States than in Europe. From Jaeger's collection of the published cases of amputation at the knee-joint, it appears that, out of thirty-seven, about twenty-two have had a favourable, and fourteen an unfavourable result.

"At the Western Medical Society of London, October 23, 1857, Mr Lane gives the particulars of the case of a child, aged eight, where he performed amputation at the knee-joint; and I believe he is the first surgeon who in England thus operated, leaving the articular surfaces entire. Since then this special operation has been frequently and successfully practised.

"We come now to consider the question of *amputation at the knee.* The steps of the operation are similar to that at the knee-joint, save that the articular surfaces of the femur are removed. To Professor Syme, of Edinburgh, is certainly due the credit of first practising this operation, and placing it in a prominent position by his writings, as already referred to; the point, however, of originality in the matter must be conceded to Malgaigne, for he first suggested it: "If, through disease of the knee, you could not have recourse to disarticulation' (writes this practical surgeon), 'perhaps you would obtain a similar result by cutting the thigh as near as possible to the condyles, and covering the osseous surface with a large anterior flap. This very simple idea is in accordance with the most useful rule of amputations, viz., to operate as far as possible from the trunk. I can scarcely understand how it has escaped the observation of surgeons to the present day.' I believe Mr Fergusson to have been the first surgeon who performed this operation in England. It was on the 17th of May, 1845, and the patient was a man aged twenty-four years: the particulars of the case will be found published in the 'Lancet,' July 19th of that year.

"It is most interesting that in the last edition of his Practical Surgery, 1857, he alludes to this case, operated on years before, in these satisfactory terms:—'I have seen this young man repeatedly since, and he was at King's College Hospital a few weeks ago. Without exception, I deem the stump equal to any I have ever made in the thigh. He has repeatedly walked forty miles a day, with a very indifferently made artificial leg, and once accomplished 120 miles in three days, without the slightest damage to the tissues.' Since this time Mr Fergusson and other surgeons have frequently repeated the operation, and with excellent success."

Mr Butcher then gives a graphic report of two cases in illustration of the different modes of operating. He then makes some cautionary observations on the selection of cases and points to be attended to in the treatment of them, and thus sums up:

"Briefly to recapitulate those directions for excision of the knee-joint, which I have laid down, and would still insist upon:—

"1. *The judicious selection of the case.*—The bones not being diseased far beyond their articular surfaces; while, if upon section found to be a little more than had been expected, the part should be gouged out, or an additional thin slice removed; but, if to a greater extent, amputation should be at once resorted to, and, as recorded in my first memoir, with a hope of excellent success. Again, the Report goes on to show that amputation may be performed some days after excision, should any unfortunate circumstance in the managment of the case have arisen to demand it. In this same paper seven instances are recorded of amputation of the thigh, and all made rapid recovery, save one.

"2. *The H incision should be preferred.*—The perpendicular strokes placed well back, so as to allow all fluids and discharges to drain off—far more effective and safer than any opening made in the popliteal space.

"No portion of the flaps to be curtailed, though they may be thinned, of any thickened fibrinous matter or diseased synovial membrane; the latter, particularly, should be clipped away with a strong scissors. All ligamentous fibres, both around and within the joint, should be cut through, and the extremities of the bones fairly freed and exposed.

"3. *The patella should be taken away in all cases, whether diseased or not,* and then the section of the bones, well thrust out in front, should be made with 'Butcher's saw' from behind forward, due attention being paid to the axis of the thigh-bone at the time of its division.

"4. *All bleeding vessels should be tied, or any that have sprung and retracted should be drawn out and secured,* so as to guard against intermediary hæmorrhage.

"5. *While the patient is yet on the operating table, the limb should be placed in the horizontal position, either by gentle and steady traction combined with pressure of the cut surfaces of the bones backwards, or, if necessary, the division of the hamstring tendons.* Their support behind, in every case, I look upon as of great value; therefore their section must be looked upon as a last expedient towards straightening the limb.

"6. *During the adjustment of the bones, great caution should be exercised, that their surfaces be throughout their extent in contact, and that no soft parts intervene.* The flaps should be then laid down, and connected by suture closely throughout their transverse division, while the lateral incisions should be brought together only at their extremities by one or two points, and the central portion of each, that corresponding to the division of the bones, should not be brought in contact, but dressed lightly with lint soaked in oil, thus securing a ready outlet for the escape of fluids. The extremity should next be cautiously laid upon 'Butcher's box splint,' padded to the natural configuration of the limb, its sides elevated, foot-board applied, suitable pads introduced, and then the anterior splint laid on, taking the place of the assistant's hand, which, from the first, restrained the femur from projecting forward; then the straps buckled, the waist-band applied, and the patient may, with safety, be removed to his bed. The bed should be prepared in this way, and consist of a couple of hair mattresses laid one upon the other, evenly supported, and intervening between the upper one and the sheet a folded blanket, feather pillows for supporting the head and shoulders; the bed should be, likewise, moderately warmed, so as to prevent the patient being chilled when put into it.

"7. *The limb should not be disturbed for several days;* the length of time depending a good deal on the season of the year when the operation is performed, whether it be in the heat of summer or the cold of winter. After five or six days it may be necessary to let down the sides of the box-splint, to sop up discharge, change lateral pads and soiled dressings, &c. By the apparatus named, the facilities for cleansing the limb are so efficient, that it may not be requisite to lift the member from its support for even so long a period as three weeks, as evidenced in my own practice. Should, however, it be considered expedient to change all the dressings, the anterior splint should be steadily held back by an assistant, and the limb pressed up to it, thus guarding against any starting of the femur forwards, or displacement laterally, when lifted from its bed. When the box is prepared, freshly arranged, the limb, controlled after the manner mentioned, should be laid down, the side splints elevated, foot-board secured, and the straps over the anterior splint first tightened so as to maintain it in that position, from which it was never suffered to change. I would impress this advice still further—if the straps be unloosed for any purpose, the hand of an assistant should steadily keep the anterior splint in its position, and well pressed back, until the artificial support is again brought to bear upon it, and fastened.

"8. In cases where large abscesses form in the vicinity of the excised joint, or up along the thigh, Chassaignac's drainage tubes may be used with the best hopes of success.

"9. *The free administration of stimulants and sedatives, imperatively demanded in all cases of excision,* regulated, to a certain extent, by age, sex, temperament, and habit."

The 'Medical Times and Gazette' contains a continuation of Dr SIMPSON'S Lectures on the Diseases of Women, the special subjects being *Puerperal Mania and Puerperal Hypochondriasis.* Speaking of puerperal mania, the Author points out that the danger is in a ratio to the speed of the pulse—a pulse from 90 to 100 not implying serious results, one from 120 to 130 always foreboding danger to life. He then gives an interesting account of the ancient modes of treating insanity by amulets, drinking the waters of favourite wells, &c., and says of the treatment:

"1. *Bleeding.*—At one time the almost universal rule in this, as in so many other forms of disease, was to begin the treatment by a more or less copious venesection. All our ideas in regard to this measure are undergoing, as you well know, a perfect revolution. But even before the ideas of Medical men regarding the value of venesection in other maladies had begun to change, Esquirol and other authorities on the subject of insanity had pointed out that in the treatment of puerperal mania it was useless, or even injurious. Further experience has only served to show that bleeding is actually injurious in this kind of disease, and that patients who have been bled do not recover so readily as those who have not. You can easily understand how this should be so, when I anticipate an observation I shall afterwards have to treat of, and tell you that in the chronic stages of the malady t becomes almost always necessary to feed up the patient, and endeavour by all means to restore the vigour of her constitution; and this indication is always more difficult of fulfilment in those cases where the patient's vital powers have been to some extent reduced by a copious venesection. I would have you, then, strictly avoid bleeding any woman who happens to become the subject of puerperal mania, merely because she is insane. If there be any condition under which this rule may ever be infringed, and a partial bleeding permitted, it will be in the case of those patients in whom the symptoms lead you to fear that some inflammatory condition of the brain or its membranes coincides with the mental derangement; but such complications are assuredly extremely rare.

"2. *Vascular Sedatives.*—Bleeding is too severe a measure to be employed in any case of simple puerperal mania; but where there is great excitement, and the pulse perhaps is high, it comes to be an empirical indication of no small importance to fulfil, to reduce the excitement and quiet the exaggerated action of the heart and vascular system. Various medicinal agents may be employed with this view, such as antimony or ipecacuanha, in depressing doses; or one or two drops of tincture of aconite—or of the tincture of veratrum viride—may be administered. While thus bringing powerful deprements or sedatives to act on the central organs of circulation, external derivatives may be applied to the more distant set of bloodvessels by the application of heat to the extremities; or by tying a bandage round one of the limbs, so as to keep a large quantity of blood for a time out of circulation, thus producing all the effect of a series of large cupping-glasses. Cold applied, in the form of a douche, to the head, or to the whole body, has a powerfully depressing action, and may sometimes be employed. But not only are the general excitement and the irritability of the vascular system to be subdued; we must also endeavour to counteract, as far as possible, the superpolarity that exists in the nervous system by the administration of the various

"3. *Nervous Sedatives.*—Of these camphor was the remedy most frequently employed by Dr Gooch in the treatment of puerperal mania; and you will do well to have it in recollection as a remedy that may sometimes prove serviceable. Opium is beneficial in some cases. In others it proves of no avail. You may remmember that, in my last Lecture, I called your attention particularly to the great degree of wakefulness that sometimes precedes the attack; and, bearing that in mind, you will see that in some cases it may prove of great service to administer to the patient an anodyne which shall counteract her restlessness, and send her off to sleep. But it is often as difficult to get a patient to sleep who is threatened with an attack of puerperal mania, as it is to put to sleep a patient with commencing *delirium tremens*—sometimes even more so. A patient threatened with *delirium tremens,* as you know, usually feels sleep stealing over him in sixty or seventy hours after the commencement of the attack, whether he has got opium or not; but a patient with commencing puerperal mania may remain restless and wakeful for several days and nights before the excitability begins to subside. When once the patient does fall into a good sound sleep, however, her case becomes more hopeful, and the probability is that she will waken up

tolerably well. This kind of sleep it must be your endeavour to promote or procure. If the patient is not so violent as to forbid the use of a warm bath, and such a bath be at hand, it sometimes acts an an excellent anodyne in this disease. Medicines are oftener used for the fulfilment of this indication; and I have seen some cases where an attack of mania has been cut short by a good full opiate administered with this view. The great difficulty is to get the patient to take the medicine. Sometimes she is too mad to swallow it, and too outrageous to be controlled. Whatever may be the way in which you give the drug, remember always, as the grand rule to guide you in its administration to such patients, that it must be given in very large doses. If you expect to have any good effect from it, you must give in general not less than two or three grains of solid opium, or an equivalent dose of some of the cognate preparations. You may give it by the mouth, or in the form of an enema; or when the patient cannot or will not swallow, and will not admit of an injection, you may succeed in introducing the drug in the form of a suppository into the rectum. A suppository containing half a grain, or a grain, of morphia is one of the most convenient and efficacious means of administering an opiate, especially for the relief of pelvic or abdominal pains in cases where the stomach is too irritable to tolerate any other preparation of the medicine. But to produce any effect on a patient threatened with puerperal mania, you will require to use a suppository containing perhaps one or two grains of the morphia. Some years ago I was sent for to see a lady about forty miles from Edinburgh, the second wife of a gentleman whose first wife had died of puerperal mania. The lady whom I had come to see was still in the stage of restlessness, had been chattering continually for some days, and refused to take any kind of medicine, or to admit of the administration of opium in any form. She recognised me when I entered her room, and rebelled at once, declaring she would have none of my remedies. With some little management, however, I succeeded in passing into the rectum a suppository with two grains of morphia, with this result, that in an hour or so she fell asleep, and after sleeping about sixteen hours she woke up well, and had no reenrrence of her maniacal symptoms. In some cases you may get the patient to sleep by bringing her under the influence of ether or chloroform. I have sometimes found that a patient, after being anæsthetised by means of chloroform, has continued to sleep on, and has afterwards wakened up quite well. More frequently, however, she awakes in the same state as when she went to sleep—no better, but also with no aggravation of the symptoms. In all cases, therefore, where such remedies are not contraindicted, you ought to give the patient the chance of recovery offered by the use of opium or chloroform. In using the chloroform, you must see to have the patient fairly anæsthetised and fully asleep; and you must either remain with the patient, or have some competent person beside her, to keep up the anæsthetic condition, by making her inhale a fresh quantity of the drug whenever she gives signs of awaking, as she is likely to do every half-hour or so. In some cases, as I have shown you, you may expect by this kind of treatment to cut short an attack of the disease. I have known the remedy successful in several instances, producing at once a cure. But this happy result, alas! does not follow in many. In nine cases out of ten, after the patient recovers from the influence of the narcotic or the anæsthetic, the symptoms recur, and the malady continues its progress unchecked. In these—the large majority of cases—therefore, you must seek to combat the disease by other means."

The Author remarks that there are no specifics for the cure of the disease; that emetics, sometimes much vaunted, are rarely beneficial, but that purgatives sometimes do good. When the disease has become established, he advises that the patient should be well nourished, carefully watched, and removed from her home to a cottage where she will not be surrounded by her family. The restoration of the menstrual function is favourable to a cure; and he observes that once or twice he has effected this by the application of nitrate of silver to the interior of the uterus.

Dr Wm. Jenner contributes to the same journal an article on the Symptoms and Pathological Appearances of *Albuminoid Infiltration of the Spleen, and Lymphatic Glands*, in Children. We extract the following:

"*Case* 1.—William F. B., aged one year and one month, a fair-skinned child, with light hair and eyes. Parents in decent circumstances, formerly well off; reside in an open situation—viz., the Caledonian road.

"*Mother and her Family.*—Mother aged thirty-five, delicate; has never suffered from hæmoptysis or other sign of phthisis; has been married twelve years, and during that time has had seven children; had syphilis when pregnant with her first child; the catamenia have always appeared, at regular intervals, during the whole time of suckling. Her own family, in all its branches, very healthy.

"*Father and his Family.*—Father aged thirty-three, healthy. He is said to have lost a brother and a sister, from consumption.

"*Other Children.*—The fourth child died at the age of five months, from inflammation of the lungs and diarrhœa. Six children living, of which William is the youngest; the ages of the five are respectively—eleven years, nine years, seven years, four years, and three years. Of these, the three eldest never showed signs of rickets—the two youngest are rickety. None of the children have suffered from 'bad eyes' or from eruptions on the skin. William had for some months no other food than his mother's milk; then bread and cow-milk were added. When he came under observation, he was still at the breast.

"The following were the first notes, made September, 1859:—Extreme emaciation; never walked; cannot sit up on the floor; cries when moved; is evidently very tender. Has now been undressed, and shrieked much; the mother says, 'It is that, *i. e.*, the tenderness, which makes him cry so.' Perspires freely about the head and face, especially at night; the mother says, 'The perspiration is dreadful;' cries much at night, and kicks off the bed-clothes. Four incisor teeth.

"*Head* hot. Two months since, it was, according to the mother, 'dreadfully hot.' Forehead projects; antero-posterior diameter of the head very great. Anterior fontanelle widely open, neither depressed nor elevated. Exceedingly irritable in temper.

"*Abdomen* large, globular, tympanitic generally.

"*Bowels* now relaxed; stools very offensive, watery; at times the stools are formed, and then are not offensive.

"*Spleen* very large, moveable; reaches nearly to the crest of the ilium, but not so far inward as the umbilicus. Anterior border oblique, hard, and sharp; posterior border perceptible to touch.

"*Liver* reaches nearly to the umbilicus; inferior border too easily perceptible by touch.

"*Lymphatic Glands* in groins, axillæ, and neck, vary in size from small shots to small peas; very hard, round, moveable.

"*Chest.*—The deformity of the thorax characteristic of rickets, very great; the lateral groove, very deep; the antero-posterior diameter during inspiration, 5¾ inches: the lateral diameter at the point of greatest depression, 3½ inches during inspiration; 4½ inches during expiration.

"The softening of all the long bones is very decided, the enlargement of the ends of the bones is comparatively trifling. The bones of the fore-arm, upper arms, and thighs are bent; those of the legs are straight.

"This boy died February 16, 1860: at that time he was one year and six months old. I saw him repeatedly after the date of the foregoing notes. He was one of the cases brought down to the hospital for the purpose of illustrating rickets and albuminoid infiltration of the spleen, &c., at the time I was lecturing on those subjects.

"He continued to emaciate and lose colour; the spleen and glands increased somewhat in size; the chest deformity attained a most extraordinary degree; the tenderness became so great that he could not bear his mother to wash, dress, or even touch him; the weight of the bed-clothes seemed to cause pain.

"He continued as long as he lived to sweat profusely over the head. During the latter part of his life the stools were solid, but offensive.

"The immediate cause of his death was the mechanical impediment to inspiration offered by the softened ribs. His breathing grew 'worse and worse,' 'everything he drank took away his breath.' His mother did not consider him worse than usual for more than a quarter of an hour before his death; then she noticed his breathing was more difficult; still she had no idea he was dying till five minutes before he expired; he then seemed quite unable to 'get his breath,' and died with a slight convulsive struggle.

"The blood was examined microscopically during life; there was no excess of white globules.

"The examination of the body was made at the house of the parents.

"The head could not be opened.

"Emaciation was carried to its utmost limits; the muscles were very pale, flabby, and small.

"The chest deformity was extreme.

"The anterior margins of the lungs were emphysematous. There was some collapse of the left lung, and extensive collapse of the right lung, quite enough to account for death.

"The heart was healthy.

"There was no fluid in either pleura.

"The peritoneum was healthy; it did not contain any fluid.

"The spleen was very large, about four inches in length, and three in breadth. It was free from adhesions. It was firm and tough; its cut surface was smooth, rather pale, mottled red and almost colourless; thin sections could be made with facility, the edges remaining quite sharp; it was remarkably transparent—the more colourless the part, the more transparent—no blood oozed from the surface, and only a little red watery fluid was expressible. There was no increase in the size of the splecnic corpuscles, and no sago-like masses.

"The liver was slightly enlarged, very tough and dark from congestion; when a piece was soaked in water the blood soon escaped, and then a little transparent substance was seen to separate the lobules.

"The spleen, liver, and lymphatic glands were tested with iodine and sulphuric acid: none of the reactions characteristic of 'amyloid degeneration' could be obtained.

"The lymphatic glands were pale and hard; their cut surface pale, smooth, and homogeneous.

"The mesenteric glands had the same characters. These latter varied in size from a small shot to a small split-bean.

"In the case of William F. B., the extreme tenderness of the trunk and extremities, the profuse perspiration of the head, the desire to lie cool at night, and the deranged state of the intestinal secretions and functions, were all well marked. These symptoms are proper to rickets, and nowise connected with the albuminoid disease. Death resulted, as it so often does in rickets, from extreme softening of the ribs. At last the softness was such that dilatation of the thorax became impossible. Five months before William F. B. died, it will be noted that at each contraction of his diaphragm the softened ribs were pressed so far inwards by the weight of the atmosphere, that the lateral diameter of the thorax was diminished to 3½ inches; when the lungs were compressed, preparatory to the expiratory act, the diameter at the same part increased to 4½ inches, thus affording a good illustration of the power of the expiratory efforts by forcing air from one part of the lung to another to distend the soft parts of the thorax. After death the extent of the pulmonary collapse indicated clearly the mechanical defection that had existed during life in the apparatus for increasing the capacity of the thorax. The least obstruction to the entrance of air afforded by the presence of a little mucus in the bronchial tubes, sufficed to cause collapse of lung-tissue. No air could be drawn beyond, from defect of inspiratory power, and the mucus consequently could not be coughed out."

Another case is also reported but we shall omit it, and conclude with the Author's remarks:

"In addition to the points previously mentioned, these cases illustrate the influence of delicacy of health in the mother on the development of rickets in the child; the fact that when a woman has borne one rickety child, all her subsequent children may be expected to suffer from the same cachexia; the want of relation observed in

many cases of rickets between the enlargement of the ends of the bones and softening of the bones; the late period at which rickety children cut their teeth.

"In Case 2, from an early age the child had eaten, or rather, as it had no teeth, had swallowed, daily, meat, including pork and bacon, cheese, potatoes, and what ever beside the parents had for their food. It will be observed that no trace of tubercle existed in the body of either child.

"The emaciation of the children, and the extreme pallor of the skin and mucous membranes, were due to the albuminoid disease, and no doubt this complication tended greatly to favour the progress of the rickets. The œdema was due to the state of the blood, and to the impediment to the circulation offered by the state of the thorax. Although loss of power in the muscles is a symptom of rickets, still it is probable that the size and power of the muscles were farther reduced by the albuminoid disease. The large size the spleen attains when the seat of albuminoid infiltration (9½ ounces, the liver being 10¼ ounces in Case 2), the condition of the lymphatic glands when so diseased, and the appearances which both ordinarily present after death, are all well illustrated by these cases. The liver in both cases was found to be the seat of albuminoid disease, but the exudation was noted in the first case to be almost limited to the periphery of the lobules. During life, the hardness of the edge of the liver had led me to the conclusion that it was, like the spleen and lymphatic glands, the seat of albuminoid disease. As is so constantly the case in this disease, there was neither jaundice nor ascites. The kidneys were very slightly affected with the disease in both cases. The tendency to hæmorrhage into various tissues in the second case is worthy of note."

We observe in the same journal notes of Three Cases of *Lithotomy* by Mr Rigby of Doncaster.

The following *Case of Ovariotomy* is reported by Mr Spencer Wells, in the 'Medical Times and Gazette' of the 1st inst.:—

"In accordance with the rule I have hitherto observed of bringing before the Profession the details of every case in which I may perform ovariotomy, the following is submitted to the readers of the 'Medical Times and Gazette.' The last case recorded in this journal was the nineteenth. It was published with others in the Number of August 25, 1860.

"*Case* 20.—On February 29, 1860, I was requested by Mr McCrea, of Islington, to see a patient residing in Barnsbury park. She was fifty-three years of age, and was suffering from a very large ovarian cyst. The girth at the umbilicus was fifty-one inches, the measurement from symphysis pubis to ensiform cartilage thirty-one inches. She had been married twenty-six years; had had one child twenty-four years ago, none since, nor any miscarriages. The catamenia had been occasionally profuse, but had ceased three years ago. Her general health had been good until early in 1852, when swelling began low down on the right side, and gradually increased. She had no pain until the abdomen had acquired a considerable size in the spring of 1853, when she consulted Dr Ferguson, who advised her to wait as long as possible before being tapped. Increase had been very slow; but of late Mr McCrea had attended her for some time, owing to increasing difficulty in getting about, from slowly increasing size of the abdomen. She had lost flesh, but had a good colour and cheerful aspect. Taking all the circumstances of the case into consideration, we determined to advise still further delay; not to interfere until the pressure of the fluid began to exercise some really injurious influence, and then to meet again.

"On May 11, the fluid having increased, and as she was becoming much distressed by its pressure, it was agreed in consultation with Mr McCrea that I should tap her. This was done, and fifty-six pints of clear viscid fluid removed. After tapping, some groups of smaller cysts were felt in the wall of the principal cyst; the largest being to the right side between the umbilicus and false ribs, and adhering there. This we concluded to be sufficient indication against the injection of iodine. She was much relieved by the tapping, and remained in fair health during the summer, although the sac gradually refilled, and the smaller cysts grew faster in proportion than the large one filled. Towards the end of September she was nearly as large as before tapping, and another consultation was held, in which Mr McCrea and I fully considered the arguments for and against ovariotomy—the age of the patient, and the existence of adhesions on the one hand, and the hopelessness of mere tapping or iodine injection on the other—and after fairly putting the risk before the patient and her husband, it was determined that I should perform the

"*Operation.* — Accordingly, on October 16, Dr Cribb having administered chloroform, and Dr Althaus, Mr McCrea, and Dr Routh kindly assisting me, I removed the cyst. Although the adhesions to the parietes were very extensive, and much firmer than in any case I had met with before where I had done more than make an exploratory incision, I was able to remove the whole through an incision only four inches long, midway between the umbilicus and symphysis pubis. A small portion of adhering omentum was detached; a long peduncle from the right side of the uterus easily secured; the left ovary examined and found healthy; the peritoneal cavity cleansed carefully from a little blood and viscid fluid from a cyst which had escaped into it; and the wound united by hare-lip pins passed through the whole thickness of the abdominal parietes, including the peritoneum, and by superficial wire sutures. As soon as the wound was closed, the clamp (which had been used to secure the peduncle temporarily) was removed, after the application of a ligature below it.

"*The Progress after Operation* was very satisfactory, Mr McCrea and Dr Cribb carrying on the plan of treatment we agreed upon most assiduously. There was never much pain, though sickness was troublesome. Occasional enemas, containing twenty drops of laudanum, were given, and warm linseed poultices kept applied to the abdomen. The pulse varied from 96 to 112, and for some days there was considerable flatulent distension of the intestines. I removed the hare-lip pins on the 19th, when the wound was found to be accurately united. On the 21st the bowels acted freely, after an enema of warm water. On the 22nd I removed all the superficial sutures. The ligatures were still firm on the peduncle, and did not separate until the fourteenth day, namely, October 30. When I saw her on November 2nd, she was eating and sleeping well, and walking about the room. I saw her again on the 23rd, when she was quite well, and in excellent spirits, although she had been up the greater part of the night with her husband, who had been very ill. The cicatrix was quite firm, the appetite good, the bowels acted regularly, the urine passed naturally, and she was beginning to gain flesh. On the 26th she called, with Mr McCrea, upon Dr Ferguson, who was much gratified at the success.

"The interesting features in this case are the age of the patient, the large size of the cyst, and the extreme firmness of the adhesions, which rendered the rapidity and completeness of the recovery really remarkable even to those who have been surprised at similar recoveries before under careful nursing and simple treatment.

"The cyst was shown, on the evening of the day it was removed, at the meeting of the Pathological Society. It consisted of one very large cyst, which had contained between forty and fifty pints of fluid, and of a number of groups of smaller cysts, growing in and from the walls of the principal cyst, and weighing about eight pounds.

"This being the twentieth case, it may be well to state that the general result of my experience of ovariotomy since my first case, in 1858, has been as follows:

12 in Hospital Practice.	8 recoveries,	4 deaths
8 in Private Practice.	5 ,,	3 ,,
20 cases	13 ,,	7

"When it is remembered that many of the women who are now alive and in good health were in an utterly hopeless condition, these facts are surely a sufficient answer to the question, 'Is Ovariotomy Justifiable?' I may add, that a patient in her 43rd year, from whom I removed a large ovarian tumour in October, 1859, was safely delivered of a child on the 2nd of November, 1860, under the care of Mr Ridsdale, of Euston square. Mother and child have gone on well."

The 'Lancet' continues Dr Pavy's Lectures on *Diabetes*, from which we will make an extract next week.

Dr Ward continues in the same journal his remarks on *Scurvy*, and Dr W. Pirrie communicates to the same journal some observations on *Favus*. We extract the following statistics:

"*Frequency of Occurrence.*—The disease is generally characterised by those who have specially devoted their time and attention to the study and treatment of cutaneous affections, and by those who have recorded their experience of it in general practice, as being very rarely met with in England. Thus we find Erasmus Wilson, in his treatise on Ringworm, writing, 'In the course of my long experience with the St Pancras Infirmary, I have not seen more than six cases of favus;' and Willis, in his account of the disease, states that 'several months will often elapse before a single case of the trichosis (porrigo) lupinosa is observed among the thousands of out and in-patients who present themselves at the different hospitals of the metropolis in the course of every week.' Jenner, Hutchinson, and others all agree in describing it as of very rare occurrence.

"From all these statements, it must be inferred that the opportunities of studying this skin affection in the English metropolitan hospitals are very few, and at long intervals of time.

"If now we turn our attention to the accounts from Ireland, we find Dr Corrigan writing in 1845, that in his experience of it in that country 'it is a very rare disease.' Dr Naligan also gives it as his opinion 'that this is a rather rare affection,—appearing, however, from the observations of those who have written specially on it, to be more common on the Continent and in Ireland than in England.' He further remarks—'When I first wrote on this disease in 1848, my experience was drawn from a limited number of cases: since then, however, I have had under my care a comparatively large number of examples—twenty-three.' This was written by Dr Neligan in 1852, so that in the space of four years there came under his charge twenty-three cases of favus.

"Having learned so much from the individual experience of well-known authorities in the largest fields of observation in England and Ireland, we come, in the course of our investigations on this point, to ascertain the rate of frequency in Scotland. The opportunities of studying the complaint in Edinburgh must be very different from those enjoyed by observers at the English metropolitan hospitals, for Dr Bennett, in a commentary on a case of favus quoted in his 'Principles and Practice of Medicine,' says, 'The disease is so common in Edinburgh, that the wards are seldom free from one or more examples of it in various stages.' The truth of this statement will be at once seen by a glance at the subjoined table, showing the number of annual admissions for favus into the Royal Infirmary of Edinburgh over a period of ten years:—

Cases of Favus admitted into the Edinburgh Royal Infirmary.

From Oct. 1,	1849,	to Oct. 1,	1850,	admitted	14
,,	1850	,,	1851	,,	9
,,	1851	,,	1852	,,	10
,,	1852	,,	1853	,,	16
,,	1853	,,	1854	,,	15
,,	1854	,,	1855	,,	10
,,	1855	,,	1856	,,	15
,,	1856	,,	1857	,,	4
,,	1857	,,	1858	,,	13
,,	1858	,,	1859	,,	14
				Total,	120

"The rate of frequency in other parts of Scotland will be gathered from the following tables, compiled from the annual reports of the Glasgow and Aberdeen Infirmaries, and showing the number of admissions into these institutions for a period of nine years, and the manner in which they were distributed over that term.

Glasgow Rl. Infirmary.

Year.		Cases.
1851	admitted	0
1852	,,	0
1853	,,	0
1854	,,	0
1855	,,	2
1856	,,	1
1857	,,	8
1858	,,	3
1859	,,	1
Total		15

Aberdeen Rl. Infirmary.

Year.		Cases.
1851	admitted	4
1852	,,	2
1853	,,	2
1854	,,	1
1855	,,	2
1856	,,	4
1857	,,	0
1858	,,	5
1859	,,	4
Total		24

"From the first table it will be seen that there are very frequent opportunities of studying the disease in the Edinburgh Royal Infirmary; and, from the second, that the number of examples of the affection admitted into that hospital has much exceeded the number admitted during an equal period of time into the Glasgow Royal Infirmary. This is a very strange fact, seeing that the population of Glasgow more than doubles that of Edinburgh, and the number of admissions of all kinds during each year into the two hospitals is very nearly alike. It also appears that, although the population of Glasgow exceeds that of Aberdeen by at least 300,000, and although the annual admissions for all kinds of diseases into the Glasgow Royal Infirmary double those into the Aberdeen Hospital, still the number of cases of favus treated in the Aberdeen Royal Infirmary over a period of nine years, exceeds that treated in the Glasgow Royal Infirmary during a like period by nine. The fact of the disease having been for many years so much rarer in Glasgow than in Edinburgh, and even less frequent than in Aberdeen, notwithstanding that its population more than doubles that of Edinburgh, and is nearly five times greater than that of Aberdeen, would lead one to suppose that there must be some peculiar local influences which powerfully predispose a people to the complaint under consideration. Whether the great difference in the number of examples admitted into hospital in the towns already named be owing to peculiarity of climate, to greater excellence or defect of sanitary arrangements, to any difference in the food of the people, or to any diversity in their habits, I cannot say; but statistics establish the fact that, in the most populous towns in Scotland, favus has for many years been of much less frequent occurrence than in other towns containing only one-half or one-fourth part of the number of inhabitants. For the last nine years there have been, on an average, nearly three admissions every year for favus into the Aberdeen Hospital; and this is a proportion which, although it may not entitle us to call the disease very common, at least justifies us in not characterising it as of very rare occurrence in this locality. As the estimated population of Aberdeen is only a little above 80,000, it necessarily follows that the number of skin diseases of all kinds admitted into the hospital is but small; but one circumstance which struck me much on looking over the reports since 1850 was, that the number of cases of favus exceeded that of herpes, lapra, ecthyma, pityriasis, and some other akin affections which are generally regarded as very common.

"The disease must be of very frequent occurrence in France, for Rayer, who describes the disease as commencing in a pustule, says: "Tinea favosa is the most common of all pustulous inflammations of the scalp."

We extract from the 'Dublin Medical Press' the following case of *Aneurism of the Thoracic Aorta*, by Dr G. W. EGAN, occurring in the practice of Dr Geoghegan and Dr Benson:

"Cornelius C., æt. forty-eight, a coalman, accustomed to lifting heavy bags of coal, admitted October 11th, 1860.

"*History.*—He was of intemperate habits, but in general enjoyed good health. About *two months before admission* he got, as he describes it, a heavy cold, with hoarseness and ill-defined pain in left side of chest, all of which came on rather suddenly in one day: these continuing, along with other symptoms to be presently described, he came into hospital.

"*State on Admission.*—There is a good deal of *emaciation*, which has been progressive during two months. In *deglutition* there is some slight difficulty, with a sense of soreness about upper part of sternum. *Dyspnœa:* This is not particularly marked, but he has been of late liable to get out of breath on making slight exertion. *Cough:* This symptom is very troublesome, especially at night; it cannot be said to be of the laryngeal kind, but is accompanied by stridor deeply seated in the chest. There is a copious *expectoration*, which from the beginning has been tinged with blood, rather in patches than in streaks, and usually of a rusty colour. *Pain* is of only one kind, deep seated in the left side of the chest, and not lancinating nor paroxysmal. The *pulse* is distinctly weaker in the left carotid, but there is scarcely any appreciable difference at the wrist. There is nothing abnormal in either *pupil*. *Inspection* of the chest reveals a very slight prominence over the cartilages of the second and third left ribs, and upon *palpation* a distinct double impulse is felt in the same place: upon *percussion*, dulness is found extending from the left clavicle downwards to the fourth rib, and from the middle of sternum outwards on the same side for about five inches. There is also dulness posteriorly over a space of two inches square at the inferior angle of the left scapula: otherwise the left thoracic region is normally resonant. On *auscultation*, a double sound, closely resembling that of the heart, and without any soufflet, is heard over the tumour: the respiratory murmur is nearly absent on the entire of the left side, and the respiration in the right lung is complemental. The *veins* were found to be enlarged in two situations—the cutaneous ones over the tumour, and the left jugulars in the neck. The *heart-sounds* were normal and in normal position, but rather weaker than in health.

"*Progress of Case and Treatment.*—The patient was ordered to rest quietly in bed, and to use the following diet: breakfast, four oz. of bread, two oz. of milk; dinner, two oz. of meat, two oz. of bread, four oz. of milk; supper, same as breakfast. 9th day: The impulse over the tumour having meanwhile considerably diminished, the entire posterior surface of left lung was found this day to have become rather suddenly dull, but at the same time the respiratory murmur had become much more audible than before; no bronchophony could be heard. Ordered—

℞ Liq. antim.
Syr. scillæ, āā ℥ss.
Tr. opii, ℥j.
Mucil. acaciæ, ℥j.
Aquæ, ℥vi. M.

Capiatur cochl. medium ter in die.

"A blister also was applied posteriorly over the dull part.

"13th day.—No improvement has taken place. A slight roughish *bruit* was found to-day to accompany the first aneurismal sound. Another blister was ordered above the situation of the last.

"15th day.—Some obscure crepitus of a humid kind was found in the dull part of the lung.

"21st day.—The cough, dyspnœa, and sanguineous expectoration have all increased; the strength has become greatly prostrated, and the countenance dark and livid. At the same time, the dulness behind was considerably diminished, and the respiratory murmur is more audible than before. Ordered chicken-broth, and a little wine-and-water.

℞ Sp. ammn. arom.
Liq. Hoffm., āā ℥j.
Miat. camph.
Aq. menth. pip., āā ℥ss. M. ft. haustus.

"One or two ounces of blood to be taken by cupping from the front, and the entire chest to be dry-cupped.

"22nd day.—The voice has changed, suddenly assuming a curious guttural tone, and all the symptoms are aggravated.

"23rd day.—The patient died to-day, having apparently become gradually asphyxiated.

"*Autopsy, twenty hours after Death.—Exterior of Aneurism.*—It was a tumour of a globular shape, twice the normal size of the heart, extending from the first rib above to a level with the fourth below, and from the second and third ribs anteriorly to the necks of the same posteriorly, and, though in contact with these parts, not pressing upon them. The left lung was strongly adherent to its left surface, and to parts of its anterior and posterior aspects.

"*Interior of Aneurism.*—Upon opening it in front, it was found to contain a mass of irregularly laminated fibrinous coagulum, rather larger than the closed fist, presenting in its central part the appearance of black-currant jelly, and adherent to all the parietes, except inferiorly and posteriorly, where two large orifices were found, the upper extremities of the ascending and descending parts of the arch, about two and a half inches from one another: the tumour, therefore, seemed to be a dilatation of the transverse portion of the arch, extending itself in every direction except downwards, and more forwards and upwards than posteriorly: from its parietes two shallow sacs with thin walls were found to project, one anteriorly, about an inch and a half in diameter, the other towards the right side against the lower ten segments of the trachea, behind which it sent a small *cul-de-sac;* owing to the partial absorption of the walls here, those segments were visible in the interior of the tumour. It, therefore, belonged to the class of mixed multilocular aneurisms.

"*Effects of Pressure.*—The trachea was pressed about an inch and a half from its course towards the right side, and was somewhat narrowed in calibre. The left bronchus was pressed downwards and partly occluded. Along with the trachea the right vagus and the œsophagus were displaced towards the right side, and the left phrenic was pushed forwards. The course of the left pneumogastric was very remarkable, and if any similar anatomical derangement be on record such cases must be exceedingly rare: when the mass of contained fibrine was removed from the tumour, *it was found to traverse the cavity of the sac* in a direction from above downwards and forwards, three-fourths of the distance from the anterior surface, and having a small portion of the coagulum intervening between it and the posterior wall; it entered directly through the upper wall, but passed out through the lower by a very oblique slit; at the upper opening it retained its normal shape, but at the lower was spread out into filaments, and about a quarter of an inch above its exit gave origin to the recurrent, which, passing out through the same slit, turned sharply upwards and backwards, superficially involved in the posterior wall of the sac: those parts of the nerves within the sac were decidedly atrophied. There is only one way of accounting for this anomaly: the tumour enlarging upwards and forwards, pressed against the nerve; the latter by a process of progressive absorption made its way through the walls, and, when once it was in, the sac, expanding in front of it, left it towards the posterior part of its cavity. The three large branches of the arch were narrowed to about two-thirds of their normal calibre, and were involved in the thickened parietes of the upper surface of the sac, passing almost horizontally through them, the brachio-cephalic and left carotid, each for about one inch, and the left subclavian for an inch and a half.

"*Heart, Lungs, &c.*—The heart was completely normal, except one small calcareous patch in an aortic valve: each of the ventricles contained a moderate-sized fibrinous clot. The left lung was somewhat congested posteriorly, and rather smaller than natural. The mucous lining of the trachea, especially about the bifurcation, and of the left bronchus, was intensely vascular.

"*Comments.*—Some difference of opinion existing among the pupils as to the comparative size of the arteries, and the amount of their pulsatile force, Dr Benson remarked, that to arrive at a satisfactory conclusion on this subject, it is necessary to apply not only the same hand, but the same finger, to the two in succession, as the two hands, like the organs of special sense, are frequently dissimilar in the amount of sensibility they possess. In the present case, considering the amount of pressure and tension to which the recurrent nerve was subjected, as found after death, the symptoms referrible to laryngeal spasm seemed very light in comparison with those usually present in such cases. During the last few days, and more especially at night, the paroxysms of dyspnœa were frequent and severe, causing the greatest alarm to the patient, and dread of suffocation, yet seeming to depend more on the pressure upon the trachea than on the condition of the recurrent, as he referred his distress in breathing to the top of the sternum, not to the larynx. The extraordinary course which the pneumogastric took attracted particular notice, and was minutely examined by Professor Power. The absence of hypertrophy in the left ventricle led Dr Benson to consider the aneurism of very recent formation; and the history of the case supports this opinion, notwithstanding the size and structure of the tumour. The treatment adopted was that recommended by the late Dr Bellingham; and although it was quite unsuccessful in this case, it seems to be making a favourable impression on two other cases at present in hospital under Dr Benson's care, the history of which will be given on a future occasion."

(Continued at Page 398.)

POOR-LAW PAY.—The Union of Epsom contains one thousand patients, and involves journeys of five miles on the part of the Medical Officer to visit many of them; he is remunerated with the magnificent salary of twenty-six pounds, being at the rate of sixpence a case. Fortunate Galen! Perhaps the Guardians of the Epsom Union imagine that he is sufficiently paid by living near Epsom Downs: it is to be hoped that the Doctor is also a bit of a racing character, and manages to make out his income by a neat book on the Derby. Cheltenham cannot afford to give more than sixpence a case, while merry Islington pays a Doctor for looking after four thousand patients at the munificent rate of threepence a case! Halstead offers fivepence, and the Medical Officer of that union has to travel six and a half miles to gain his salary of ten pounds for attending four hundred and fourteen patients. On the other hand, it is fair to state that some unions pay much better; for instance, Elham offers twenty-eight pounds for eleven patients,—a perfect Dorado for the Doctor.—Dickens's 'All the Year Round.'

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

THE MEDICAL CIRCULAR.

WEDNESDAY, DECEMBER 12, 1860.

ANCIENT AND MODERN LONGEVITY.

The desire of a long life is natural to man, and the means of accomplishing it have consequently formed a favourite topic of speculation in all ages. The most notable philosophers have loved to expatiate on the good conduct of life, and the most successful empirics have been those who have vaunted most loudly their possession of an infallible secret of longevity. Plato, Plutarch, Cicero, and Bacon did not deem this subject beneath the dignity of their contemplations; and, on the other hand, the insolent Paracelsus and the fanatical Cagliostro found it a facile source of popularity and success. How many more vulgar pretenders to the art of prolonging life there have been, it were difficult to enumerate; or how many recipes have been invented to accomplish the same result is not catalogued in our memory. From the gymnastics of the Greeks, the incantations and talismans of the astrologers, the tea of Count St. Germain, the elixir vitæ of Cagliostro, the magnetism of Mesmer, down to the tincture of the sun, and the pills of Jenkins and Old Parr, the world has never been without its panacea for the restoration of lost vigour and the prolongation of life.

It has been a favourite habit to bewail the degeneracy of modern races of men, and to impute blame to our mode of civilisation as the cause of the alleged physical depravity. We are not concerned to defend our civilisation, which is undoubtedly characterised by numerous imperfections; but we cannot believe that, on the whole, it is answerable for that excessive depreciation of the value of human life which the majority of authors assign to its influence. The facts of the argument have not been fairly exhibited; and we have been rather content to rely upon startling and curious statements, than to compare the evidence with truth-seeking and impartial minds.

We omit from consideration the registers of longevity contained in the Sacred Records, because the facts they disclose come under a different order of criticism from that which is suitable to a Medical periodical: we shall allude only to those lists of longevity which are usually paraded in books, and which are intended to convey the notion that the sages of past times lived to a much more advanced age than the men of more modern centuries. It is generally assumed also that the quiet and serenity supposed to accompany philosophical disquisition is favourable to the prolongation of life, and that to this cause must be attributed the extraordinary length of years attained by the Hellenic sages. We do not intend to dispute any general propositions of this nature; they are easily made, and as easily denied. The argument of ease as against exercise may appear to some a plausible one, whilst there will be many who will argue with equal conviction on the other side. The force of vitality cannot be comprehended in a well-turned period, nor imprisoned in an arithmetical formula.

The facts, however, upon which it has been sought to construct a theory of the superior longevity of the men of past times are exceedingly few and, in their nature, exceptional. The lists usually given rarely contain more than a hundred names: Haller, however, who exhibited most diligence in collecting this kind of evidence, and whose labours made the quarry from which his successors have carried away their selected specimens, has stated that up to his time there had been 1111 instances of persons who had lived more than 100 years. The figures are somewhat singular; and we fear that the evidence of the age, in a large majority of the instances, would scarcely bear a rigorous investigation. The most remarkable instances of longevity in these lists occur, however, among modern men, of whom the two most conspicuous examples are our own countrymen Parr and Jenkins

Among the ancient Greeks the evidence is very scanty, and is confined chiefly to philosophers, poets, and sophists; to the Platos, the Solons, the Gorgiases, and the Anacreons of those days. It gives us no estimate of the longevity of the tens of thousands of the populace who lived in the narrow streets and mean houses of Athens and the other Greek cities, and who were cut off by fevers and plagues in successive epidemics, as they were in Europe during those happy times of a romantic imagination, the Middle Ages.

If we glance at the other side of the question, we shall remark some curious facts which will tend to diminish the importance of the tables of ancient longevity. Some statistics on this subject were published in our Journal last week. It appears that in the Workhouses of the Stepney Union alone, there are at the present moment not fewer than 69 persons whose ages average eighty years, and 292 with an average age of seventy years. These Workhouses probably comprise more persons whose ages exceed eighty years, than are contained in all the existing records of Hellenic longevity. It must be further remarked, that these English people are *paupers:* and what that word means, as descriptive of an early life of struggle, privation, misery, sorrow, and, too often, of vice and drunkenness, we can, each of us, but too well comprehend. These are types of the lowest class of our population; and yet among them we find a longevity which, if it had been narrated of ancient Greece, or Rome, or Palestine, as occurring under similar circumstances, would have been received as the most convincing testimony of the superior length of life of the old races.

Similar facts were recorded a few weeks since with reference to the inmates of the West London Union House; and there can be no doubt that the facts now reported of the Stepney Union are merely representative of similar facts in all the other Union Houses of the Metropolis. If inquiry were made, we should not be surprised to find that in the Workhouses alone of this Metropolis there were, at least, *five thousand persons* whose ages averaged eighty years. But the paupers constitute only a small section of our population; and it would be interesting to obtain a knowledge of similar facts in respect of the other classes, the members of which are more favourably situated with reference to all those advantages and accommodations that are favourable to the prolongation of life. The Reports of the Registrar-General would yield valuable evidence on this interesting question.

The same number of the MEDICAL CIRCULAR that contained this information on the longevity of English paupers also recited certain facts relating to the value of life among Quakers. It appears that during the present year fifty persons of this denomination have died whose average age attained the high figure of eighty-five years!

So much for the facts; we leave the general questions arising from them to the consideration of the student. What has race to do with longevity? No doubt, very much. Our own race and the Scandinavian races generally ar reputed to be the most long-lived. How much climate? how much modes of life?

It behoves us, however, to conclude this article with the enunciation, that of all the systems, rules, and recipes that have been invented to prolong life, the most effectual will prove to be that great system of Public Hygiene which has been recently adopted in this country, and which, there can be no doubt, will in the course of a few years raise the value of human life to a standard unexampled in the historical records of our race. The speculations of philosophers and the mountebankery of quacks will alike sink their pretensions before the actual blessings humanity will derive from the general adoption of this enlightened and beneficent system.

CHELSEA, BROMPTON, AND BELGRAVE DISPENSARY.—Her Majesty the Queen, with her accustomed generous munificence, has bestowed 50*l* on this institution.

SUMMARY OF THE WEEK.

POOR-LAW MEDICAL REFORM.

Mr Griffin speaks in a tone of despair unusual to his eager spirit. He has been earnestly pressing forward the cause of Poor-law Medical Reform for several years, and at the crisis of the agitation finds that the Poor-law Board will give no countenance to his scheme. He is also in want of funds, and it would seem that the agitation must, for a time at least, be suspended. A man's claims to respect must not always be judged by the result of his exertions; and most assuredly no advocate has deserved better at the hands of the Poor-law Surgeons than Mr Griffin. He has been indefatigable and zealous beyond most men; and if he be doomed to fail, it will not be on account of the absence of these qualities. We refer our readers to a correspondence which Mr Griffin has had with the Poor-law Board, and which explains the present position of the question.

MR PINCHING AND THE COLLEGE OF SURGEONS.

As the representatives of Professional feeling, bound by our office to notice every infraction of Professional honour, we cannot avoid adverting to the evidence given by Mr Pinching when under cross-examination in the recent trial of the cause Dent *v.* Denison. Every Medical man who perused that evidence must have felt the blush of shame burning in his cheek as his eye ran over, line by line, the disgraceful confession which was wrung from the lips of the witness. He admitted that he had clandestinely written letters, having a base and filthy purport, to the young daughter of a gentleman who had received him into his confidence not only as a Medical adviser, but as a friend, and at whose table he had frequently dined. This kindness and hospitality he had treacherously betrayed, and was so conscious of his baseness that he dared not attempt to justify his conduct. Other parts of the evidence showed that he claimed 962*l.* for attendance upon his patient from the 27th January to the 26th April, besides a further sum of more than 70*l.* for drugs represented to have been sent by his son. It appeared also that he had made the mistake of antedating his attendance, increasing his claim thus by about 40*l.* Now, Mr Pinching is a Member of the Royal College of Surgeons; how long shall he so continue? How long shall the Members of that College be insulted by the companionship of one who is thus scandalised by his own mouth? If the Council do their duty, they will at once take the necessary steps to vindicate the respectability of the College.

THE EDITORSHIP OF THE BRITISH MEDICAL 'JOURNAL.'

The widowed and wheezy 'Journal' of the Association has taken to herself a fresh spouse in the person of Dr Markham, for better for worse, for richer for poorer. The nuptials have been quietly celebrated; no speeches having been made, nor pie-crust broken. If the old lady had gone off in an asthmatic fit, it would have been far kinder than to drag along a fretful existence by the side of a gay young gallant like Dr Markham. How he will writhe under her peevish discontent and irritating petulance! We pity the gentleman; but he sought his fate, and he can blame only his own imprudence. It is quite time that this Journal was discontinued. It has none of the merits of a private undertaking, and all the disadvantages of an Association organ. It is really cruel to put a clever man to such thankless work as the editing of this periodical, and we do hope that the Members will yet see the propriety of cutting short its existence.

THE DEATH OF SIR HENRY MARSH.

Death has laid low another honoured Member of the Profession, smiting him suddenly in the height of his fame and in the middle of his work. Whilst in the act of setting out to visit his patients at an early hour in the morning, Sir Henry Marsh was suddenly struck with a fit of apoplexy, and fell to the ground. He was not immediately insensible, but was able to describe his fall, and to point to his leg, which he had injured. Unconsciousness, however, soon supervened, and he died in a few hours. Sir Henry Marsh enjoyed for many years the first practice in Dublin as a Physician, and had earned the warmest esteem both of the Profession and the public. Thus he has fallen in harness, like poor Todd, Bright, and Addison; killed, perhaps, by anxiety and over-work. He has left a Psychological Treatise for publication: it will be received with kindness, and read with a melancholy interest.

HONOUR TO DR COPLAND.

We understand that certain friends of the great medical cyclopædiast propose to do him honour by some public expression of their admiration of his genius and labours. It is premature this week to enter into details, the proposal being yet in an inchoate form; but we shall revert to it on another occasion. We have no doubt that the Profession would gladly embrace an opportunity to do honour to so illustrious a brother.

THE CHIEF JUSTICE OF THE COURT OF COMMON PLEAS ON THE LAW OF LUNACY.

A remarkable decision has been pronounced by the Chief Justice of the Court of Common Pleas, in an action for False Imprisonment, brought by a girl called Penny, who had been confined in the Staines Union Workhouse as a lunatic. The plaintiff had been a maid-servant in the household of Dr Clarke of Staines, and was alleged to be singular in her conduct. On one occasion she was very violent, quarrelled with her mistress, attacked her, and sang hymns and prayed on the stairs. On Dr Clarke's return home, he deemed it proper to send her to the Workhouse, and applied to the Overseer, who wrote an order in these terms: "Please receive this girl of unsound mind." After she had been in the house about three weeks, she was allowed to go; the Surgeon, Mr Curtis, expressing his belief that she was of sound mind. Upon this point we give no opinion; our object being only to call attention to the summing up of the Judge, who said:

"The defendant's plea was, that the plaintiff was a lunatic, and was dangerous to himself and his family. No man had a right to cause a person to be imprisoned as a lunatic unless he was dangerous, and required immediate confinement. It was for the jury to say whether the plaintiff was really so dangerous a person as had been represented on behalf of the defendant, and whether she was a lunatic at the time she was confined. He could not see that the evidence went to prove any dangerous lunacy. The witnesses for the defence had no doubt stated what took place on the 29th in a very different manner from what the plaintiff had stated, but from the time the policemen came in there was no allegation of any conduct that could be considered dangerous. The incoherent language used by her was certainly not proof that she was likely to be dangerous. If the jury thought that she had been imprisoned as a lunatic without cause, they would give such damages as they considered her entitled to, for the degradation she had suffered. If they thought there were grounds for considering her a lunatic, then they would find their verdict for the defendant.

"The jury returned a verdict for the plaintiff; but considering that there were some grounds to induce Dr Clarke to act as he had done, they would not give more than 10*l.* damages."

If his Lordship mean, what his words appear to express, that no lunatic can be legally confined unless he be "dangerous," then five-sixths of the Asylums in the country should be closed, and the Lunacy Acts have been misinterpreted and shamefully perverted. If, on the other hand, he mean that no person can be sent to a Workhouse for immediate protection on the presumption of insanity, instead of an Asylum under a regular order, then it becomes Union Surgeons to be exceedingly careful, or they may unwittingly render themselves liable to serious legal proceedings. This case should be remembered. Our quotation is taken from the 'Observer.'

RELIGIOUS INTOLERANCE.

We call the attention of our readers to a well-written letter, in the next column, commenting in severe terms upon the religious intolerance of the Governors of the Radcliffe Hospital at Oxford, who have required that the candidates for the office of House-Surgeon shall be members of the Church of England. Looking at the doctrinal character of that University, we are only surprised that it was not made an additional condition that the candidates should belong to the Puseyitish section of the Anglican Church. The illiberality of imposing any condition with respect to the religious creed of a candidate for a Medical appointment could have been practised only at the historical seat of religious intolerance. A man's

skill as a Surgeon cannot be either enhanced or impaired by his religious profession; and as it is our duty to confer the benefits of our science upon all men alike without reference to class or creed, so it is unbecoming to our Profession that every class of Practitioners but one should be ostentatiously excluded from office at a public institution. Supposing a similar rule to prevail at all other Hospitals and Dispensaries, it would be necessary that the members of every religious denomination should found a Hospital for their own poor, with Medical Practitioners professing the same creed to attend to them. Nothing could be more uncharitable, unsocial, or pernicious.

RELIGIOUS INTOLERANCE,

AS EXHIBITED IN THE QUALIFICATIONS REQUIRED IN ELECTING THE HOUSE-SURGEON TO THE RADCLIFFE INFIRMARY AT OXFORD.

(From a Correspondent.)

In the 'Oxford Chronicle' of the 17th November is an advertisement for candidates to fill the office of House-Surgeon to the Radcliffe Infirmary, requiring that he shall be a Member of the Church of England, as well as a Member of the Royal College of Surgeons and of the Society of Apothecaries. Does membership of the Church of England presume that a man must have been baptised, confirmed, and have taken the Sacrament of the Lord's Supper at least four times in the year, as commanded in the twenty-third canon, and that he should attend the Dominical services, and the feasts and fasts of the Church? It is as well to understand what is the meaning of being a member of the Church of England. Never having heard that such a religious qualification is considered necessary in any of the Metropolitan or Provincial Hospitals and Infirmaries, it took me greatly by surprise why this exception at Oxford should be the rule of electing a Medical Officer to the Radcliffe Infirmary. Is a Physician or Surgeon more or less fitted to exercise his profession because of his creed? Is the rule founded on monastic, corporate, geographical, or ecclesiastical peculiarities, so that a Surgeon who is fit to be a House-Surgeon in Edinburgh or Paris, is unfit at Oxford, unless he has the double qualification of Membership of the Church of England and the College of Surgeons? The rule savours strongly of priestcraft, of the old leaven of religious intolerance and persecution. The Royal Colleges of Physicians and of Surgeons of London, Edinburgh, and Dublin, do not claim the right of exacting from their candidates their religious creed or faith. They proclaim that they who have passed their medical examinations are fitted to practise and teach the art and science of Medicine. They do not demand whether a candidate is a Member of the Church of England; whether he assents and consents to each and all the Thirty-nine Articles, the doctrines of the Prayer-Book, the Homilies and Canons, or to the Augsburg Confession of Faith. Do the Governors of the Radcliffe Infirmary really believe that adhesion to the Thirty-nine Articles will enable the House-Surgeon to set a limb, to extract a stone, and to do his duties to the sick, in every respect better than if the peculiarity of his metaphysics should tempt him to doubt whether the Articles are in strict accordance with Scripture?

The science of Medicine is not fettered by the formularies of churches and sects,—it is the same under every clime and country; it owes no allegiance to Lords Spiritual and Temporal,—to Kings, or Priests, or Pope; it has for its basis the truths of philosophical investigation, and its object the alleviation of human sorrow, pain, and infirmity. Any gentleman of right moral principles, common humanity and industry, will fulfil the duties of his office, whether his creed is Anglican, Presbyterian, Catholic, or Independent.

A few years ago the Legislature abolished the Test and Corporation Acts; the Catholic Emancipation was carried, and, recently, the Jews admitted into Parliament; the whole constituting a series of progressive enactments to establish the great, just, and generous principle that no man shall be prejudiced in his civil rights by reason of his religious creed.

The Healing Art extends its God-like blessings to all alike—to the Jew and Gentile, to rich and poor, to bond and free. Its maxim, "Homo sum, humani nihil a me alienum puto;" "Tros Tyriusve mihi, nullo discrimini agetur." The good Samaritan did not hesitate to give balm and oil to the wounded man; he did not first ask whether he belonged or not to a particular sect of the House of Israel,—whether he was Samaritan, Sadducee, or Pharisee. The Holy Gospel mentions no special claims as appertaining to, nor confers miraculous gifts of healing on any favoured disciples or sects of men, but bestows its benefits alike to the tribes of Levi and Judah—to the stranger within and without the gate, to the Jew and Gentile.

If our Northern stars of the Presbyterian Church,—if the Hunters, Bells and Monros, the Symes or Millers of Edinburgh—if Dupuytren, Velpeau or Ricord, Scarpa or Tiedmann, and countless others who have adorned science and surgery, were to offer themselves as candidates for the House-Surgeoncy of the Radcliffe Infirmary, they would be rejected! they are not orthodox in the hallowed precincts of Oxford!! Did the liberal Sultan exclude from his armies and hospitals the Christian dogs, the Doctors of England and France? The Mussulman has shown a more enlightened philosophy than the Christian of Oxford: the Koran was not insisted upon, though the Thirty-nine Articles must be. Let us learn a brilliant example from the pious benefactor, Sir Jamesetjee Jejeeboy, who built and endowed a hospital at Bombay for the sick poor of all nations. He did not impose the Parsee faith on the Surgeons of the Hospital. Who succoured the stricken and destitute Syrians? The philanthropist Jew, Sir Moses Montefiore, and his philanthropic coadjutor, the amiable and pious Quaker, Dr Hodgkin.

Sauntering round the new beautiful Museum of Natural History at Oxford, I was delighted to see statues dedicated to the memory and honour of the immortal men of all ages, nations, tongues, and religions; a Walhalla of genius! In a Byzantine building—the primitive style of architecture of Christianity—are statues erected to Hippocrates, the Father of Medicine; to Aristotle, the mighty Stagyrite, the Father of Natural History; and to his disciple of a later age, the celebrated Cuvier. Linnæus and Priestly, Davy and Dalton are there, who have shed lustre on the kindred sciences of Medicine, Botany, and Chemistry. There is Leibnitz, the rival of our heaven-descended Newton; and there Watt and Oersted, who have revolutioned the world by their discoveries in steam and electricity; and there is the persecuted Galileo, imprisoned by cruel and ignorant priests, because his celestial discoveries did not harmonise with the religious dogmas of the ruling ecclesiastical polity of the day. Are not these statues suggestive of generous emotions? Here are illustrious Pagans, Catholics, Anglicans, Presbyterians, Unitarians, Quakers, and Independents, brought together in the great Temple of Science. The worshippers of an unknown god, the believers in the ancient oracles, Christians of different denominations are here honoured as the chosen vessels of intellect. The Thirty-nine Articles and the Canons have no supreme rule in this sanctuary of mind.

The requirements of the candidates for the Radcliffe Infirmary are incompatible with the age we live in: such requirements are exploded in Catholic Belgium, France, and now in Italy, in America, and Turkey; they are unbecoming a liberal, an enlightened, a Christian country. It is unworthy of the Governors of the Radcliffe Infirmary to impose a religious restriction on any Medical Officer who is otherwise fitted for the duties of his office; and it is earnestly hoped that the Governors will rescind that obnoxious requirement, will conform to the more generous and just tendencies of the times, and give that right of religious freedom to others which they claim for themselves.

R. W., Physician to a Hospital.

Nov. 28th.

THE SPIRIT OF THE PERIODICALS.

(Continued from page 395.)

We reproduce from the 'Dublin Hospital Gazette' the following *Fatal Case of Poisoning by Oxalic Acid*, reported by Dr M. H. Collis:

"On the 10th October, at twenty minutes to one o'clock p.m., I was called out to Stephen Hawkins, a College porter, aged sixty-five, who had taken the greater part of an ounce of oxalic acid about half an hour previously. He had been found by his son vomiting, and moaning, and straining on the night chair in probably ten minutes after he took the poison. Medical assistance was almost immediately obtained from Mr Graham's establishment in Westmoreland street. Large quantities of chalk mixture had been given before I saw him, and, as he was rapidly sinking, about eight ounces of brandy. The stomach-pump was also prepared, but not used until I came, as vomiting had been copious and repeated. When I saw him, he was becoming rapidly insensible; his face and chest were deadly pale, and covered with perspiration; his pulse was faltering, very weak, and soon became intermittent; his respiration was slow and sighing, and the vomiting had ceased. I immediately poured a tumblerful of brandy down his throat, which for a moment revived him, and then used the stomach-pump, and drew off some thick chalky fluid. The above symptoms, however, became rapidly aggravated, and I desisted from the use of the pump; his pulse failed, his respiration ceased for several seconds, and within five minutes from my entering his room he was to all intents dead. By drawing forward his tongue, and alternately raising his arms to his head and depressing them to his sides, at the same time compressing the thorax laterally, I kept up artificial respiration for a few minutes. The heart's action had, however, ceased, and the body became cold with great rapidity. The mucous membrane of the mouth and tongue were pulpy and colourless, as if chemically destroyed by the poison; and on examining them the next day this condition was more evident. The body had then become very rigid, the muscles singularly hard, and even the tongue felt like a board. A post-mortem examination was not made, at the request of the family; and as the cause of death was abundantly proved, there was no excuse for insisting upon it.

"I ascertained that he had purchased two half-ounce packets of oxalic acid at a druggist's, and that he acknowledged to having taking them. The envelopes were found (properly labelled) and empty. He had mixed the acid in a small tumbler of water, and swallowed it in so concentrated a state as must have required him almost to chew it. A small quantity undissolved was found in the tumbler. The fluid he vomited was of a darkish green. It had been thrown out before I saw him, as had the remains of the poison; but their nature was verified by Mr Graham's assistant, to whom Hawkins spoke before he became insensible, and to whom he confessed the fact of his intention to destroy himself.

"The only point of interest in this case, in a toxicological point of view, is the conection which existed between the large and concentrated dose of the poison and the rapidity of the fatal syncope. Much less than an hour would appear to have elapsed from the time the poison was swallowed to the cessation of the heart's action. Copious vomiting, and even soma diarrhœa, failed to eliminate the poison: indeed, the occurrence of diarrhœa must be looked upon as a bad sign, showing that the poison has passed downwards into the intestine, and that the action of antidote or stomach-pump will come too late.

"When oxalic acid is taken in such large and concentrated doses, it would appear to act not only as a violent local irritant, but as a powerful sedative. The heart's action in this case ceased to be perceptible before respiration failed; and to the same sedative cause is to be attributed the sudden and remarkable lowering of the general temperature."

We make the following extract from the 'Journal of Practical Medicine and Surgery,' as containing Professor Simpson's latest views on *Dressing Wounds:*

"After glancing at the practical questions, towards which M. Bonnafont's attention was more especially invited in Edinburgh, Mr Simpson concludes with some remarks on vesico-vaginal fistulæ, and the treatment of wounds consequent on operations.

"'This last session, I had eleven cases of vesico-vaginal fistulæ, some of these very large, in the hospital ward under my care. These eleven patients were all cured in succession, by one operation each,

ron wire being used for sutures. Now, if under these circumstances primary union was effected eleven times, why should not surgeons, more expert than I profess to be in the handling of many surgical instruments, close their amputation and other wounds by the first intention also? I am inclined to think that the great reason why they do not effect this, and thus cure their cases in days instead of weeks, is simply the presence of setons and ligatures in the depths of their wounds, and the use of dressings. I am satisfied that almost all, if not all wounds would heal far more rapidly without any dressings whatever, with nothing but metallic sutures in their lips, and no bandages, compresses or local medication, not even cold water—for water dissolves the crusts which Nature labours to form, and undoes what she is attempting to do. I have seen this in amputations most convincingly. The breath of a pair of bellows cools a wound, when necessary, far more effectually than any lotion, or wet or greasy application. No dressing was used in any one of my eleven cases of vesico-vaginal fistula; had any been resorted to, I should have failed in one or more of these operations.

"'I therefore used no kind of apparatus, but merely pared and revivified carefully the lips of the fistula, brought the edges together with slender iron wire, (I never used silver,) and usually removed the ligatures on the tenth day. A flexible pewter catheter was left in the bladder for the first eleven or twelve days, changing it daily. By this very simple method, I had the good fortune to cure eleven cases of fistula, some of which were very large, in the course of one session.'

"Mr Simpson, however, remarks that from this sweeping proscription of topical remedies, and dressings in general, he excepts carbonic acid. Our readers are aware that, some five years ago, Mr Simpson published, in his 'Obstetric Memoirs and Contributions,' a paper on Carbonic Acid Gas, and its applications to surgical practice. What then was a mere suggestion has since become a practical fact, and we recently described the benefits derivable from this agent as an analgetic and cicatrizer."

We extract the following article on *General Paralysis* from the same journal:

"The study of the manifestations of incipient insanity is highly interesting, inasmuch as it is chiefly at this stage that mental disease may possibly derive benefit from medical interposition. In a medico-legal point of view it is equally important to ascertain whether certain censurable acts are the result of a morbid perversion of the cerebral functions, or belong to the class of punishable crimes or misdemeanours. Medical pathology still presents much uncertainty; and when praiseworthy efforts are made by eminent men to throw some little light on so obscure a subject, it is a duty to lose no time in inviting public attention to their researches.

"We must, therefore, notice here the work which Dr Forbes Winslow, the eminent British specialist, published this year in London, 'On Diseases of the Mind and Brain,' and also three communications forwarded to the Academy of Sciences on general paralysis, by Messrs Baillarger, Billod, and Brierre de Boismont.

"General paralysis is one of the most common and unforgiving diseases of the brain. It attacks men in the prime of life, and carries them to a premature grave after having progressed through stages of the most melancholy degradation. At first the complaint is insidious, and it not unfrequently happens that the symptoms by which it is ushered in escape notice. It is, therefore, all-important to distinguish such symptoms, and among them M. Baillarger indicates, as deserving of attention, hypochondriac delirium.

"Paralytic hypochondriacs, says the learned physician of La Salpêtrière, believe that their organs have been changed, destroyed, or entirely obstructed. They assert, for instance, that they have no mouth, abdomen, or blood; or that their fauces are closed, the stomach quite full, &c. Some are under the impression that their food escapes by unusual passages, and gets under their skin or their clothes; others assert that they cannot open their mouths or eyes, that they can neither swallow nor pass water, and some protest that they are dead, and obstinately refuse to take any nutriment. M. Baillarger having found this form of delirium very common among paralytic subjects afflicted with melancholic mania, naturally watched with care the same kind of delirium when it occurred in persons who presented no symptoms of general paralysis, and he has observed that many such persons were subsequently attacked with general paralysis. Without, however, considering this as a necessary consequence, M. Baillarger asserts that hypochondriac delirium is a serious presumption of the future occurrence of general paralysis, and adds one element to the prognosis of the disease.

"'It must, of course, appear strange,' says M. Baillarger, 'that a peculiar form of delirium should be an indication of future disorganisation of the brain; but, as far as general paralysis is concerned, this is the second fact susceptible of the same interpretation. Bayle's interesting and valuable researches have made it abundantly plain that delusions marked by much elation, or the *manie des grandeurs*, are in many instances the premonitory sign of paralytic dementia. Upwards of thirty years ago, an eminent author recorded his opinion that this variety of delirium is especially noteworthy, inasmuch as it may often allow the practitioner to foretell several months beforehand the occurrence of general paralysis. The fact has now been placed beyond doubt by numberless instances; and if it is really the case that the delusion of fancied supereminence is of such great prognostic value in monomania, why should not the same be true also of the hypochondriac delirium of melancholics?'

"At a subsequent meeting, M. Billod, chief physician of the Asylum of Sainte-Gemmes-sur-Loire, assented to M. Baillarger's assertions, but gave them more general scope. Thus he endeavoured to show that M. Baillarger's remarks on hypochondriac delirium as a forerunner or a pathognomonic of general paralysis are equally applicable to all forms of melancholic delusion, whatever their nature—for instance, to fancied persecution—and that the important fact adduced by the Professor of La Salpêtrière refers more to the variety of melancholia attended with stupor, than to the peculiar nature of the delusions by which it is accompanied.

"M. Billod related, as an illustration, the case of a captain of infantry, on half-pay, who died in 1855, from the progress of general paralysis, and who, ten or twelve years before, had been tormented by imaginary persecution, and the fear of being poisoned.

"The patient, fancying himself to be surrounded by armed enemies who had a design on his life, at first displayed a disposition to violence; and then, imagining himself threatened with the most cruel tortures, he attempted to commit suicide. This state of excitement was followed by stupor; the action of the tongue became embarrassed, and dementia set in with the signs of general paralysis. At no period of his life was this individual subject to hypochondriac preoccupations.

"M. Billod agrees with M. Baillarger and most authors, that general paralysis may be characterised as well by melancholy and depression, as by elation with large delusions; and he has even found both forms of mental aberration combining in the same subject to induce a mixed mental condition, in which notions of ideal wealth and grandeur were associated with the chimerical dread of persecution. This gentleman, in the course of the last six years, has twice had the opportunity of directing the attention of his assistants to cases of general paralysis, in which the patients, while believing themselves to be possessed of untold wealth, fancied at the same time that they were surrounded by enemies desirous of despoiling them. In other instances, the demented are impressed with the notion that their large possessions and high position excite in all directions envy and jealousy, whence arise many imaginary annoyances, and the chimerical fear of the darkest conspiracies for the destruction of their happiness.

"M. Brierre de Boismont has sought for the first indications of general paralysis in the perversion of the moral and affective faculties. Of all moral perversions, that which has especially struck M. Brierre de Boismont is klepto-mania; in the second place, he considers as highly suggestive the perpetration of shamefully licentious acts, in contrast with previously correct habits of life. M. Brierre de Boismont relates the following instance, which appears to us interesting:

"'A merchant,' said he, 'being threatened with a prosecution for fraudulent bankruptcy, was placed in my asylum, for what was supposed to be feigned insanity. His friends informed me that several months before he had been observed frequently to leave his house in a mysterious manner, and without any apparent object; that he had been watched, and that he was found to be in the habit of repairing to infamous houses—a thing entirely foreign to his principles and former decorous mode of life. For eighteen months the patient remained under my care, and I examined him several times to form a correct estimate of his mental condition; but he preserved a strange sort of silence, which baffled inquiry. When much pressed with questions, he would merely reply, 'I have acted as people generally do in business; all will be explained and justified.' One morning, however, as I was visiting the wards, he came up to me smiling, and, with a marked stammer, requested the loan of *four millions*. From this time the progress of general paralysis became very rapid, and two months after the poor man died in the most advanced stage of paralytic fatuity."

NEW MAGISTRATE FOR CHESHIRE.—Alfred Aspland, Esq., M.R.C.S., Dukinfield, has been made a magistrate for the county of Chester; so that Dukinfield will now have a local and resident magistrate.

GENERAL CORRESPONDENCE.

SPECIAL HOSPITALS.

To the Editor of the Medical Circular.

SIR,—I am directed by the Special Hospital Protest Committee to request a gratuitous insertion of the enclosed important Professional document in your Journal.

I am, &c. W. H. FLOWER, Hon. Sec.
32 Queen Anne street,
London, W.

"We, the undersigned, are of opinion that much detriment to the public and to the Medical Profession arises from the modern practice of opening small Institutions, under the name of Hospitals, for particular forms of disease, *in the treatment of which no other management, appliance, or attention is required*, than is already supplied in the existing General Hospitals.

"The practice is injurious, First, because in the maintenance of numerous small establishments the funds designed for the direct relief of the sick poor are wasted in the useless multiplication of expensive buildings, salaries, and Hospital appliances, and in the custom of constantly advertising to attract public attention.

"Secondly, because the public is led to believe that particular classes of disease can be more successfully treated in the small special Institutions than in the General Hospitals; an assumption directly contrary to evidence, the fact being that the resources of the General Hospitals are in every respect superior to those of the special Institutions alluded to.

"Thirdly, because it is essential for the interests of the public, with a view to the efficient education of Students preparing themselves for the practice of the Medical Profession, that all forms of disease should, as far as possible, be collected in the General Hospitals to which Medical Schools are attached.

"As an example that the evil referred to is increasing, we regret to observe that an attempt is being made to set on foot a Special Hospital for the treatment of Stone and Diseases of the Urinary Organs. We desire to express our opinion that such an Institution is especially unnecessary: the existing General Hospitals provide ample accommodation for the treatment of all these maladies; *no case is ever refused admission into them;* there are no diseases which receive more care, attention, and skilful management; and there are no men in this or any other country who have greater experience in treating them than the Surgeons of our General Hospitals."

Signed by—

SIR BENJAMIN C. BRODIE, Bart., President of the Royal Society.
JOSEPH H. GREEN, F.R.S., President of the Medical Council.
THOS. MAYO, M.D., F.R.S., President of the Royal College of Physicians.
J. F. SOUTH, President of the Royal College of Surgeons.
SIR J. LIDDELL, M.D., C.B., F.R.S., Director-General Navy Med. Department.
J. B. GIBSON, M.D., C.B., Director-General Army Medical Department.
And 504 other Practitioners, London and Provincial.

THE VACCINATION FEE.

To the Editor of the Medical Circular.

SIR,—By an Act of Parliament passed a short time since, we are informed, that for the future, before the Medical Student can be fully qualified to practise, he must obtain a Certificate to perform the very awful operation of Vaccination from one of the Public Vaccinators, on the payment of one guinea. Why this additional tax on the often slender resources of the Medical Student?—is not the Registration fee sufficient? It will be highly inexcusable if the Medical Students of England do not rise to a man, and, with united effort, boldly and calmly oppose this iniquitous tax. They have done well in the past agitations for right; let them show that an English spirit of justice still burns within their bosoms.

I am, &c. CHARING CROSS.

(The foregoing letter calls attention to a subject of great interest to Students. We subjoin a copy of a Memorial that has been agreed to by the Students of Manchester, and that might be ad-

vantageously adopted by the Students of the other Provincial and Metropolitan Schools.)

(Copy.)

To the Council of the Royal College of Surgeons of England.

We, the undersigned, Students of the Manchester Royal School of Medicine and Surgery, beg to call the attention of the Council of the College of Surgeons to the injustice which we labour under, owing to the regulation concerning vaccination issued by the Council in August last.

By this regulation all who present themselves at the examination for the diploma of the College are required to possess a certificate of proficiency in vaccination. This certificate can only be obtained by attendance for six weeks at an educational vaccination establishment, which in Manchester is situate at a considerable distance from the hospital. In addition to the time spent in this attendance, all students are obliged to pay an extra fee for the certificate, an expense which, since the regulation is made retrospective, those who commenced their professional education previously to the present session by no means anticipated.

We beg to submit to the consideration of the Council, that by far the greater proportion of us have already been instructed in the theory and practice of vaccination by the surgeons with whom we have been resident, many of us throughout a period of several years, and that these surgeons, both from their general professional education and from the number of vaccinations they have annually to perform, may be considered fully qualified to give this instruction. The student who has for years been constantly engaged in the practice of vaccination under the superintendence of such a surgeon, can hardly be expected to derive much benefit from six weeks' teaching by the Educational Vacciuator.

The only advantage which this regulation affords to those who obtain the diploma of the College is, that they are thereby rendered eligible as Poor-law Medical Officers and as contractors for vaccination ; but as, with the present scale of remuneration, few of us are likely to become candidates for such appointments, we beg to submit to the Council that it is unjust for all to be obliged to spend time and money in obtaining this certificate.

Your memorialists, therefore, pray either that the regulation in question may be rescinded, or that a certificate of proficiency in vaccination from a duly-qualified surgeon may be recognised by the Council, as is the case with the certificate of practical midwifery.

And your Memorialists will ever pray, &c.

(Signed.)

POOR-LAW MEDICAL REFORM.

To the Editor of the Medical Circular.

Sir,—Permit me to trespass on the pages of your Journal to lay before the Poor-law Medical Officers the following correspondence, which proves that the Poor-law Board are determined to continue in their present course, and oppose all redress of the grievances of the Medical Officers. Under these circumstances it must rest with the Profession whether I am to continue the course I have hitherto pursued, and endeavour to carry our Bill through Parliament, or let things remain as they are. I am willing to go on ; but unless I am supplied with the sinews of war, my personal efforts will be of little avail. Since the issue of the last pamphlet, I have received only 14*l.* 15s. 6d., whereas the cost for the stamps alone expended on that occasion was upwards of 13*l.*, and the printing and other expenses amount to about 40*l.* more. I have materials ready for another pamphlet, collated principally from the reports of the Poor-law Board, which will prove the necessity for the proposed change ; this I am desirous to send to each Member of Parliament, but the printing, &c., will cost at least 50*l.* What is 100*l.*, or even 500*l.*, among 3,000 Medical men, in comparison with the prospect before them of obtaining upwards of one hundred thousand pounds per annum ?

The Poor-law Board, in their letter, say, "that the Consolidated Order of 1847 has received the approval of a Select Committee of the House of Commons, expressly appointed to inquire into its operation and results." On referring to the Report I find the following :—"The Select Committee appointed to inquire into the mode in which Medical Relief is now administered in the different Unions in England and Wales, and to ascertain whether any additional facilities might be afforded the poor in obtaining Medical aid." In the above there is not one word about the Consolidated Order of 1847, let alone the Committee being expressly appointed, &c., &c.

In the first resolution of that Committee is the following:—"That no sufficient evidence has been adduced before your Committee to justify their recommendation of an entire change in the present system of Medical Relief as administered under the Consolidated Order of 1847, by means of which the poor have derived greater facilities in obtaining Medical aid than they were enabled to do previous to its promulgation." The Poor-law Board have chosen to view the above as an approval of their Order, but I think your readers will look upon it as almost the reverse, and I have little doubt had the evidence we now possess been laid before the Committee that they would unhesitatingly have recommended a remodelling of the present system.

In the last session of Parliament, Lord Palmerston promised the House that a Committee should be appointed to inquire into the administration of the Poor-law Board: I trust that Committee will be a searching one, and that Medical men will prepare themselves to lay evidence before it ; and I feel sure, if all other branches of the Board are conducted in the same manner as the Medical Department, that a material change in the constitution of the Board will be recommended.

I am, &c., Richard Griffin.

12 Royal terrace, Weymouth,
December 3, 1860.

Copies of Letters.

12 Royal terrace, Weymouth,
October 31, 1860.

My Lords and Gentlemen,—I have the honour to forward you three copies of a Draft Act of Parliament on Poor-law Medical Relief. I trust the Bill is drawn in such a way as to meet the views of your Honourable Board : should, however, this not be the case, I shall feel obliged by your pointing out what you desire on the subject, as I feel sure the Medical Officers will yield on many points in order to obtain your support and place the whole affair on an equitable basis.

I am, &c., Richard Griffin.

The Poor-law Board.

Poor-law Board, Whitehall, S.W.,
November 19, 1860.

Sir,—I am directed by the Poor-law Board to state, that they have carefully perused the draft which you have prepared, and have submitted to them, of an "Act of Parliament for the Proposed Redress of the Grievances of the Poor-law Medical Officers." The Board, after full consideration of all the provisions of the proposed measure, regret to inform you that it is not one to which they are able to give their support.

I am, &c., C. Gilpin, Secretary.

R. Griffin, Esq., J.P.

---

12 Royal terrace, Weymouth,
November 22, 1860.

My Lords and Gentlemen,—I have the honour to acknowledge the receipt of your letter of the 19th inst., in which you state, "The Board, after full consideration of all the provisions of the proposed measure, regret to inform you that it is not one to which they are able to give their support." May I ask the favour of your informing me the principal points of the Bill to which you object ? The main feature of the Bill is the payment of the Medical Officers in proportion to the number of cases they attend, and the distance they have to travel,—do you object to this ? If so, what other mode would you suggest ?

The next point is the amount of payment proposed,—do you object to this ?

The qualifications of the Medical Officers, and the extra Medical fees to which they are to be entitled, are proposed to be left for arrangement to your Honourable Board, in conjunction with that of the Medical Council,—do you object to this ?

In a former letter I stated that the Poor-law Medical Officers were willing to concede much in order to secure the support of your Honourable Board ; with this spirit on their part I respectfully trust you will not keep them at arm's length, but will endeavour to meet their views, and place this much-vexed question on an equitable basis. Possibly you would prefer to bring in a Bill as a Government measure, and thus carry out the views of the Right Hon. T. Sotheron Estcourt, who stated to the deputation of Poor-law Medical Officers as follows:—"The matter ought not to continue in its present state ; and if I continue in office, I shall use the best means in my power to put this question on a better footing, and make such arrangements as will be satisfactory both to you and to the public."

I have the honour, &c.,

The Poor-law Board. Richard Griffin.

Extract from the Report for Dec., 1839, p. 249.

Colonel Wade writes, "I do consider it exceedingly desirable that the experience obtained during the last four years of the various systems which have been in operation for affording Medical Relief should, with as little delay as possible, be applied towards establishing, not in this district only, but throughout the kingdom, uniformity of plan, uniformity of principle in respect of the amount of remuneration. The plan to which I give a decided preference is that of a 'pauper list,' combined with the 'per case' provision for casual sick. Medical Relief is in its nature and consequences—in fact, in every point of view, one only excepted—unlike all other kinds of relief. It is true that, like any other kind of relief, it is injurious to the independence of the receiver ; but it does not, like all others, in addition to this, tend to create again the destitution it relieves. Many will be poor again because they have found an easy access to relief ; but no man will be sick again because he has, without difficulty, obtained the aid of the doctor."

Poor-law Board, Whitehall, S.W.
December 1, 1860.

Sir,—I am directed by the Poor-law Board to acknowledge the receipt of your letter of the 22nd ult. on the subject of the draft of the Bill which you have prepared for the "Proposed Redress of the Grievances of the Poor-law Medical Officers."

The Board, in reply, direct me to state that they have already informed you, in their letter of the 19th ult., that they could not consent to the provisions of your Bill.

The Board direct me to add that, in their opinion, no sufficient reasons have been adduced to justify a departure from the general principles of Medical Relief as administered under the Consolidated Order of July 24, 1847, and which has received the approval of a Select Committee of the House of Commons expressly appointed to inquire into its operation and results. Under such circumstances, the Board do not consider that any advantage can result from discussing the provisions of the Bill which you have submitted to them.

I am, &c.,

W. G. Lumley, Assistant-Secretary.

R. Griffin, Esq., J.P.,
12 Royal terrace, Weymouth.

Zoological Gardens.—A young male example of a very scarce and little-known animal of the swine family—the Babirussa—has just been received by the Zoological Society, and is now placed in their gardens in the Regent's Park. The adult babirussa is remarkable for the extraordinary development of his tusks, which turn upwards and backwards, and form a semicircle nearly meeting the jaws again. The whole contour of the animal is also very different from that of the true pig. The babirussa is a native of the island of Celebes, in the Indian Archipelago, and obtained its name from the extraordinary idea of the Malays that it originates in a cross between a pig (*babà*) and a deer (*russa*). The present is believed to be the second individual that has been brought to Europe alive, a previous specimen, obtained by Sir Edward Belcher during one of his exploring voyages, having lived for a few weeks in the Society's gardens in 1841.

An Astro-Meteorological Society is announced by a Mr White, of Camberwell, with the avowed object of instituting a rigid investigation of the weather and its changes, on which such vast interests depend, with a view to draw confident inferences as to future storms, &c. Since a British Meteorological Society already exists which aids and countenances such investigations, and includes all the men of eminence in this department of science, the new society, so announced, must be regarded with doubt until further names and particulars are published.

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.

DEC. 1ST.—LITHOTOMY—NEW MODE OF OPERATING.—MR WOOD. LITHOTRITY—STAPHYLORAPHY.—MR FERGUSSON.

LITHOTOMY.

In the aim and object to relieve human suffering inflicted by the presence of stone in the bladder, ingenuity and invention seem inexhaustible, and to have no present termination. It is true, the lapse of 200 years of surgical experience and practice of innumerable fresh modes of reaching the bladder for the removal of calculi have brought the practice of lithotomy within narrow and simple limits in our time. We have at length settled down to two modes of performing lithotomy. If the lateral operation did not possess the intrinsic merits and decided advantages of safety, expedition, facility, and success, it would not be upheld by its claim to antiquity, nor by its surgical traditions, which carry us back to the earliest history of the science. The median operation, although a revival, has claims especially its own. From the successful results attending this operation, and its simplicity, the claims of the median operation will, no doubt, always be acknowledged; and the rivalry of the median and lateral operations for lithotomy will have their several advocates, and give their several triumphs. No doubt, the origin of the lateral operation may be traced to the distance and depth of the parts to be reached by section, and the limited space of the perinæum through which to obtain a safe route from the surface to the bladder. It is effected by a cutting operation through the perinæum externally until the bladder is reached at its neck. The median admits of a more limited space, since the knife is not wholly depended upon in its performance. Moreover, there does not prevail any objection amongst the advocates of the median operation, if unavoidable, as is often the case, to division of the rectum, and also of the levator ani; which objections, no doubt, influence a preference to the lateral operation amongst its advocates. The median operation is divided into two distinct stages, and two distinct operative actions; the first stage being effected by incision, and the second by dilatation or rupture. This necessarily implies a slow operation, which is no objection under the influence of chloroform; and the bulb of the urethra is often wounded. Mr Fergusson, who may perhaps be considered the most successful operator for lithotomy of the present day, prefers, and always performs, the lateral operation. In making a few observations upon the operation for lithotrity to-day, which we shall presently record, he stated that he did not consider there was more danger attending the operation for lithotomy than for lithotrity, and that death rarely resulted in the present day from the first operation. This fact was the more worthy of regard, since lithotomy was truly an operation in the dark. After the first superficial section, all was done out of sight. The empire of vision was relinquished, or, to speak more correctly, became unavailable, and the tactile sense assumed its place. When such a condition of things occurs, it is not surprising that new expedients are resorted to, and invention is on the rack. Surgery gives no parallel instance of an operation performed in obscurity, except its sister operation lithotrity. The subject in hand has induced these remarks. We regret we were not early enough to witness Mr Wood's new operation, or to hear only a few words of his explanation upon the occasion. We regret this the more, since his lucid explanations, assisted by diagrams, prove highly instructive. It being the first operation of the kind upon the living subject, we shall have other opportunities of witnessing its merits. The novelty was the use of a new instrument, which Mr Wood designates the "Dilating Staff." We understood him to say that the external incision, made in a semi-lunar form to gain room on the left side of the perineum, being conducted into the groove of this dilating staff as far as the prostate, the finger is then thrust between its blades, which dilate the prostate, and thus reaches the bladder. We shall have more to say on this subject on a future occasion.

LITHOTRITY.

This patient, a middle-aged man, was placed under the administration of chloroform. After removing several fragments of stone, Mr Fergusson made a few remarks upon the comparative merits of lithotomy and lithotrity, and upon the administration of chloroform during the operation of lithotrity. He spoke of the instruments used. The lithotrites, of which he showed three different sizes, he said he had used many years. They were smaller in size than the lithotrite usually adopted. With his new instrument, armed with a rack instead of the screw, the lithotrite scoop, he brought away a considerable fragment, amongst several smaller ones. He said the operation was attended with various results, depending upon the state of health or disease of the patient, upon the quiescence or irritability of the bladder and urethra. Some bore the operation of lithotrity much better than others; but in all, great irritation, and sometimes inflammation, was induced, attended with alarming symptoms. The immunity from danger attendant upon lithotrity, he did not consider to be greater than upon lithotomy. The process was tedious, and required a frequent repetition of the lithotrite, the irritation augmenting upon each application, and the patient's sufferings were frequently very great. Some Surgeons, Mr Fergusson said, do not administer chloroform during lithotrity, as it prevents the patient giving notice, by "shouting out," if other soft parts are included in the lithotrite, in place of the stone. He said, he would advise those who have not confidence that they can discriminate the difference between a hard stone, and the soft membranes or follicles of the bladder, when within the grasp of the lithotrite, not to attempt to perform the operation of lithotrity. It was pleasing to witness the facility and precision with which these lithotrites were managed, and the successful results.

STAPHYLORAPHY.

This patient, a young woman eighteen years of age, suffered under great deformity from cleft palate. She had at some early period been operated upon for hare-lip. The fortitude she displayed under a prolonged and necessarily tedious operation was remarkable. It was a complicated case; the cleft, extending through the soft and hard palate, required careful and painstaking management. The speculum used by Mr Fergusson on this occasion seemed to be a very superior instrument for the purpose. He alluded to the usual difficulties of the operation, which, he remarked, in the present case had been greatly alleviated by the nerve and confidence of the patient, without which it would have been almost impossible to have accomplished it on so dark a day, when light was so essential to the proceedings. He adopted on this occasion a different instrument to carry the ligature, to what he had on former occasions used. He carried, by a bended, retroverted hook, the ligature from behind forwards, instead of before backwards, which he considered to be an advantage. Mr Fergusson observed that the bystanders could see but little of the process of this operation. It would appear to them a tedious, boggling, and stitching affair, and it certainly required much patience; but he had no doubt the result would speak favourably for the trouble taken, and give a satisfactory cure.

UNIVERSITY COLLEGE HOSPITAL.

DEC. 5TH.—CARIES AND NECROSIS OF TARSAL ARTICULATION—LARGE ABSCESS IN GLUTEAL REGION—EXPLORATORY OPENING.—MR ERICHSEN.

CARIES OF ANKLE-JOINT.

This patient, a young man about eighteen years of age, had suffered from disease of the tarsal articulation for many years. Under the influence of chloroform, Mr Erichsen made an incision through sinuses into the joint, and found extensive disease, implicating the os calcis, cuboidal and astragalus bones, and gouged away a considerable quantity of caries and necrosed bone. In allusion to a similar case which he had operated upon a fortnight ago, he said that patient had left the hospital cured. This case presented more extensive mischief. Mr Erichsen remarked that it was a very important point to preserve the external shell of the os calcis. If that was invaded by disease, or removed, a flat and awkward foot, with lameness, was the consequence. The whole interior structure of the os calcis may be gouged away, as in the case referred to, with little or no mischief or lameness resulting. The cavity becomes filled up with fibro-plastic or fibro-cellular growth, which in time assumes a considerable degree of hardness and firmness, sufficient to sustain any required pressure. In short, a bony deposit will ultimately on many occasions take place, and thus a useful limb is obtained.

ABSCESS IN GLUTEAL REGION.

This patient, a boy about fourteen years of age, was admitted into hospital this morning, and Mr Erichsen had made no careful examination at present. Under chloroform, upon introducing a bistoury through the posterior aspect of the hip-joint, it was followed by the discharge of full three pints of a greenish-yellow matter. The opening was sufficiently large to admit the forefinger being freely passed down into the hip-joint, which under chloroform could be carefully explored and examined. Mr Erichsen could discover no roughness or other indication of diseased bone. He said these abscesses were almost always attended with diseased hip-joint. He referred to the case of a boy which we reported a short time back, upon whom he opened a large abscess on the anterior aspect of the thigh, in which disease of the acetabulum and hip-joint existed. That case was so worn out by disease that there existed no power of reparation in the system, and he recommended his removal from the hospital to await the inevitable result. He had heard this day from his mother that the boy was fast sinking.

Mr Erichsen thought the present case would recover upon administration of tonics and generous diet.

An interesting case of fracture of the cranium, with extensive depression of the bone, had been admitted into hospital a few days back. Mr Erichsen, in alluding to it, took occasion to make some valuable surgical observations upon fractures of the cranium. The patient, an engineer, had received a blow on the side of the head from the crank of an engine, without lesion of the scalp, and was brought to the hospital. He laboured under no stupefaction or coma, and was conscious. There existed considerable irritability, and he talked loud. The blow was received on the parietal bone of the right side, and the fracture was traced by the finger over the scalp to extend to the posterior part of the parietal, perhaps over a portion of the occipital and temporal, and anteriorly to a portion of the frontal bones. The depression was formed by the inferior portion of the parietal bone, the superior overlapping it. As no urgent symptoms were present, low diet, quiet, and the application of ice-bags to the head was the plan of treatment practised. The seat of injury was very sensible and irritable to touch. On admission, this case presented no swelling or tumefaction of the eyelid; but in a few days the upper eyelid became considerably swelled and ecchymosed. Mr Erichsen attributed this to a continuation of the fracture through the orbit to the base of the skull, perhaps passing through the ethmoidal bone, and a rupture of blood-vessels, thus causing the extravasation and infiltration. In reference to the operation of trephining, Mr Erichsen observed that the old surgical axiom of trephining in depression was no longer an axiom. The operation in all cases was to be determined by the symptoms present, and not by any other stereotyped surgical rule. If there existed stupefaction, coma and unconsciousness, denoting pressure of bone, or extravasated blood upon the surface of the brain, the trephine in that case was indicated, and should be applied, and the pressure thus removed. As in this case, when no such symptoms were present, a waiting treatment was best. In this case, in a day or two after admission considerable tumefaction occurred in the seat of the injury, so as to induce a suspicion of the rupture of a branch of the temporal artery externally, or of the meningeal internally. To relieve this state of things, a figure of **T** incision was made through the scalp to allow of escape of this accumulation of blood. The flaps were dissected back, and it was ascertained to proceed from a meningeal vessel. In doing this, an escape of air-bubbles occurred, which Mr Erichsen attributed to the fracture extending to the tympanum, and a communication with the Eustachian tube being established. This patient is now becoming tranquil, and is progressing favourably and rapidly.

Mr Erichsen elucidated further the consequences and progress of fracture of the cranium, and of the influences by which they are governed. He said, the man who obtained his living by the "sweat of his brow" had a much better chance of recovery than he who lived by the sweat of his brain. A soldier or a day-labourer, whose brains

were idle and never worked, would recover, when a man striving for honours at Cambridge would have a poor chance, and would most likely sink under fracture of the skull.

OUR NOTE BOOK.

ON THE DIMINUTION OF GOUT IN THE PRESENT AGE:

A MEMOIR OF PATHOLOGICAL HISTORY.

By Dr A. Corradi, Professor of Pathology in the Royal University of Modena.

The title of this pamphlet at first considerably surprised us, as we had not at all remarked that during late years gout had assumed a retrograde course, or had, indeed, become less virulent in its attacks; but we had not proceeded very far, when we discovered that the talented Professor of the University of Modena was drawing comparisons between *ancient* and *present* times, and not between less distant periods of more modern days.

The best way we can convey to our readers a correct idea of this interesting pamphlet will be by giving ample extracts from it, which we shall endeavour to do in as nearly the Author's words as the difference of idiom will permit.

Taking it for granted that gout is now a much less common disease than it was at the commencement of the Christian era, and during the dark ages of the Lower Empire, the Author commences by saying, in the first page of his memoir:—"Ancient diseases pass away, while new ones take their place; mild ones become severe, while deadly forms of illness assume a milder character; sporadic diseases become diffused; epidemics become circumscribed; and that because either in man himself, or in his outward condition and relations, such changes take place, or such new combinations, that the older pathological states either change in character or disappear altogether."

Nothing truer. Disease not only changes its character, but sometimes disappears altogether. Where is now the plague which in the middle of the fourteenth and seventeenth centuries desolated the fairest portion of Europe? What has become of that syphilis which, in 1496, decimated the armies of Charles VIII. at Naples? We cannot recognise it in that disease which still continues to be a source of so much suffering in the present day. What has become of that dire sweating sickness which desolated Great Britain in 1485? They have passed away, and new types of disease have taken their place. Even in our own days we have seen a perfect change come over the nature of disease. Where are now the fevers that used to be cured by bleeding and low diet? And even pneumonia, which, a few years ago, was the most sthenic of sthenic affections, is now so altered in its character, that rarely, if ever, even in the largest practice, does one meet with cases requiring depletion.

At page 6, the Author quotes largely from the 'Tragopodraga'—a celebrated comic poem, written by one Lucian, about the year 120 of our era, who seems, from his vivid description of the disease, to have been himself a victim of gout.

"Neither did the Jews escape this affliction," says the Author; "and Alexandria, Athens, and Rome, the three greatest and wealthiest cities of the world, suffered beyond description from its visitation. Ptolemy Philadelphos was a martyr to gout; and Celius Aurelianus says that gout was endemic in the capital of Egypt, which must surely have been the case, if even the labourers suffered from it, as would appear to have been the case, from a letter of the Emperor Hadrian to the Consul Servianus. In Rome it was a common disorder, and most of the principal citizens suffered from it. Sylla, Augustus, and Claudius were martyrs to it; Galba was so crippled by it, that he could not put on his calzarii, nor open a scroll, nor hold anything in his hand; and Seneca, fully aware that he could not be cured, was happy if able by any means to alleviate the severity of its attacks. There have been some who, rather than suffer the agonies of this disease, have preferred to lose their feet, and some even their lives. No wonder, then, if, in trying to subdue so painful and obstinate a complaint, the physicians of those times invented the most extraordinary mixtures, and the patients resigned themselves to swallowing the most disgusting remedies."

"Hippocrates," who flourished about 400 years before Christ, "had asserted, in his Aphorisms, that eunuchs, women who still menstruated, and youths who had not yet sacrificed to Venus, did not suffer from gout;" but Seneca, about 500 years later, "complains that in his time even the women lost the hair off their heads, and suffered from pains in their feet;" and Galen, about the middle of the second century, "asserts that the eunuchs suffered from it as well as the rest of mankind."

"About this time, Diocletian passed the law which exempted from office and personal service those who were severely afflicted with gout. At Constantinople, during the Lower Empire, gout was extremely prevalent, and the Emperor Heraclius, Michael Parapinaceus, Constantinus Monomachus, Alexis Angelos, suffered severely from it. The celebrated Anna Comnena praises, in the life of her father, the Emperor Alexis, the tender care of her mother, in endeavouring by gentle frictions to assuage his agonies. It was about this period that the disease obtained a new name, and the barbarous epithet of *gout* was added to the more ancient name of podagria,—which new name some derive from the German gicht, gichten, which means agonising pain. The rapid cure of so formidable a disease was looked upon as beyond the powers of ordinary physicians," and special saints were invoked by the Christians for its relief. "St Augustin, in his work 'De Civitate Dei,' tells us that, in his time, those sufferers who prayed to St Stephen, Martyr, were always cured. We also learn from the 'Acta Sanctorum,' that many recovered their health after praying at the tomb of St Thomas Aquinas. We are told, also, in the same Acta, that St Mark, Bishop of Treveri, who was greatly venerated as a curer of gout, used to be invoked by the following hymn:

'Nam spasmo, arthritica, chiragra
Contractis quibusvis, et podagra
Mire opitularis.'
(Acta Sanctorum, Die xvi, Januari.)

"Pope Honorius IV, in 1285, summoned to Rome Thaddeus of Florence, a celebrated physician, who required and obtained one hundred ducats a day (*a*) for his services. Vladislaus IV, King of Poland, gave six thousand pieces of gold to a peasant for a supposed specific against the gout. Pontanus said: 'Hæc (Podagra) conflicti sunt Philosophi et Principes et Reges et Imperatores;' and Sydenham comforted himself and his companions in misfortune by asserting that 'Divites plures interemit quam pauperes, plures sapientes quam fatuos.'

"Gout, which, as we have endeavoured to show, was so common in ancient times, has now become generally so rare, that we may look on it as almost extinct. Even in England, its most favoured locality—the country of Sydenham, who suffered so acutely from it, and wrote so ably about it—it has considerably diminished; and the celebrated Owen, when questioned upon this subject, has confirmed our opinion, and promised documentary evidence, which, I trust, will soon reach me. In Holland, also, and in Belgium, where in Boerhaave's time gout was most common and frequent, it has now become rare. Professor Serrano, Secretary to the Academy of Medicine in Madrid, also assures me that gout is much less frequent in Spain than it was during the past century. The same I hear from Genoa, Milan, Tuscany, and the Marches. I should have wished to strengthen my assertion by figures and statistics; but the difficulty, or rather the impossibility, of getting such, compels me to rely on the information received from friends and colleagues, whose truthfulness I have no reason to doubt. From England alone, where every fact is noted, taken into account, and rigidly investigated, could I have obtained the necessary information; and I am anxiously looking forward to some statistical tables of Dr Farr, which I hope to add as an appendix to this memoir."

We thank Dr Corradi for his good opinion of British statistics; and, no doubt, most deservedly do they hold a high position on the Continent. He adds, further, that on consulting the obituary tables of England, France, Germany, and Italy, he rarely finds deaths from gout recorded. Canstatt's Jahresbericht scarcely mentions gout; and Hirsch, in his late work, 'Handbuch der Historisch-Geographischen Pathologie,' asserts beyond all doubt that gout has greatly diminished. The Author does not deny that, probably, many arthritic disorders were recorded as gout by ancient authors; but he adds: "Lucian's description of this disease so exactly tallies with the masterly account given of it by Sydenham, that it is impossible not to recognise them as one and the same complaint."

Professor Corradi is of opinion that the diminished intemperance of the present age is the principal cause of the diminution of gout. "We have no idea," says he, "of the gross excesses of the ancients both in eating and drinking. 'Vomunt ut edant, edant ut vomunt,' said Seneca. This disgusting habit was so common in his days, that it was almost considered a want of courtesy if a guest did not void his stomach before commencing a repast. Cæsar vomited before reclining at the table of Cicero; and that celebrated orator, describing Anthony, says: 'Tu istis faucibus, istis lateribus, ista gladiatoria totius corpori firmitate, tantum vini in Hippiæ nuptiis exhauseras ut tibi necesse esset in populi Romani conspectu vomere postridie!'

"Drunkenness was so common in the time of Charlemagne, that he passed laws which condemned to the *rod* those priests who should be convicted of it, and compelled the judges to attend the Courts fasting; 'rectum autem et honestum videtur ut judices jejuni causas audiant et discernant.'

"Charles V, though tired of being emperor, was not tired of good living; and, though a martyr to gout, when in the retirement of the monastery of St Justus, would not pay any attention to the exhortations of his friends and attendants, who often used to remind him of the old Spanish proverb: 'La Gota se cura tapando la bocca;' and he had so decided an aversion to fasting, that he obtained a dispensation from Pope Julius III to abstain from it, even when he was going to take the Communion."

Without saying too much for our present habits, I think we must all agree that such excessive intemperance has been long unknown: and even within the last sixty years a good step has been taken in the right direction. Professor Corradi thinks also that in the middle ages, in consequence of the unreclaimed state of the land throughout Europe, people were compelled to feed much more on animal than vegetable food. The forests abounded in wild animals, whereas agriculture was scarcely attended to; and thus, animal food being much the most abundant, it was much more freely used. Vegetables were scarce in Great Britain even in Elizabeth's reign; and Hume tells us that in those days a salad had to be imported from Holland. But, as agriculture increased, so the forests disappeared, and the supply of animal food diminished; and this has gone on progressively, till it has reached such a point in some Continental countries, that animals which we would consider as carion have been recommended as substitutes for butchers' meat. In France, especially, has the want of animal food been so much felt, that it has been seriously proposed to manufacture a *species* of *meat* in the following way:—Cattle were to be kept in good pastures, and *bled* every week, or every fortnight, or as often as they could bear it, and to as great an extent as would be consistent with their safety, and the coagulated blood sold at a cheap rate as a substitute for meat!!!

The Author is, then, of opinion that the present diminution of gout is due to the change in the habits of the nations of Europe. "In Constantinople, gout is unknown at present, though so common during the Lower Empire; but Mahometan sobriety has succeeded to the drunkenness of the Greek Empire: while in England, where much more meat is consumed, and more wine is drunk than elsewhere, gout still is prevalent, though even there it is much less frequent than of old."—Review in 'Dublin Quarterly Journal.'

(*a*) An enormous sum, considering the great difference between the value of gold now and then.

CASE OF TRAUMATIC TETANUS SUCCESSFULLY TREATED BY CONIUM MACULATUM.

Dr Corry says: On March 26, 1860, I was sent for to visit J. Russell, aged fifty-five, manager of a spirit store, residing in Ballymacarrett. On my arrival, I found him labouring under unmistakeable symptoms of tetanus, which had set in two days previously; the paroxysms were frequent and severe; there was decided opisthotonos, with precordial pain, and the trismus was so great that he could only open his mouth to the extent of half-an inch; there was, also, considerable difficulty

in swallowing, and for the last twenty-four hours he had been unable to assume the recumbent position, from an agonising sense of suffocation. Pulse 115 ; skin cool ; bowels constipated. Upon inquiry, I ascertained that about ten days ago his left hand had been crushed between two casks, by which accident a severe lacerated wound had been produced ; the injury, however, had to all appearance progressed favourably, and was now nearly healed.

Having previously had charge of two cases of this fearful malady, which I had treated unsuccessfully by the usual remedies, and having subsequently read M. L. Vella's communication to the Academy of Sciences, in Paris, on the employment of woorara in tetanus, and a paper by Mr Spencer Wells on the same subject, I was anxious to give the poison a fair trial in the present instance, and accordingly endeavoured to obtain some for that purpose ; however, not being able to procure any in Belfast, I took advantage of the suggestion thrown out by Dr Radcliffe, "that conium, the physiological action of which is almost identical with woorara, might prove a more manageable and suitable remedy :" I, therefore, ordered my patient five grains of the extract every three hours, dissolved in water, having previously evacuated the bowels by an enema of castor-oil and turpentine. After the medicine had been administered for twenty-four hours, there was a decided improvement in the symptoms ; he was now able to lie down, obtained a short sleep, and the spasms were less acute ; the pulse, also, fell to 100. Forty-eight hours afterwards, the peculiar physiological effects of the conium began to manifest themselves ; he complained of general debility, accompanied by numbness and loss of power in his lower extremities ; the paroxysms occurred at long intervals, and were greatly diminished in severity : pulse 80. Ordered the medicine to be continued, with wine, beef-tea, and eggs, to support his strength. At the expiration of a week, complete paralysis of the lower extremities had been produced ; the upper limbs were also much affected, and there was considerable difficulty in deglutition ; the spasms and rigidity of the different muscles had now all but subsided ; there was, however, still some trismus, and he slept but little : I had, therefore, to order him, in addition to the conium, an occasional night-draught of the solution of the muriate of morphia. By the end of a fortnight it was considered necessary to diminish the dose, and give it less frequently, as the muscles of respiration were becoming affected, the paroxysms had entirely ceased, and slight trismus alone remained. I now carefully watched the action of the medicine, and on the twenty-first day from its first administration was enabled to discontinue its use, as every symptom of tetanus had disappeared. A stimulating liniment was now applied to the limbs, with quinin internally, and in another fortnight he was able to return to business.

Remarks.—Notwithstanding the attention which has of late been directed to pathological investigations, our knowledge of the true nature of tetanus is, as yet, far from satisfactory ; the disease consists of a peculiar excitement of the medulla oblongata and true spinal system, occasioning severe continued spasms of the voluntary muscles, followed by imperfect relaxations. Our line of treatment should, therefore, consist in removing local irritation, and allaying nervous excitement. So far back as 1811, Sir Benjamin Brodie demonstrated by experiments the powerful sedative effects of woorara in controlling muscular spasm ; and in 1836, Mr Curling stated, in his treatise on the subject, that the poison was deserving of a cautious trial in acute cases of tetanus in the human subject. However, the great drawback to its use is the impossibility of procuring it of uniform strength, and the consequent difficulty of regulating its action. In conium, we have a much more manageable agent, possessing all the sedative powers of woorara, without its disadvantages. During the treatment of the foregoing case, I watched its action carefully, and found, that by either increasing or reducing the dose, its effects could be proportionally augmented or diminished. It would, of course, be unfair to form a decided opinion of the curative powers of any remedy from the result of a single trial ; but I must say, that, from the first, I found it so manageable and beneficial in its action, that I would have every confidence in again using it under similar circumstances."

CARBO LIGNI.

Charcoal as medicine, and for medicinal purposes, has been spoken of and extolled by scientific men in all ages. At a very early period Mons. Duval wrote his 'Appel aux Médecins sur l'Emploi du Charbon ;' and later we find a work by Dr Brachet, of Paris, on 'The Uses of Charcoal in Medicine,' upon which Dr Farr observes, "This dissertation is remarkable for its exact appreciation of its physical effects upon the human body."

In 1830, MM. Merat and Delens published a 'Universal Dictionary on Medicine and Therapeutics,' in which is contained a most able article on this preparation.

Vegetable charcoal, purified and properly manufactured from a light porous wood, is well known to the faculty to possess important properties, and to be a safe, agreeable, and effective remedy for many very troublesome and distressing maladies of the stomach and bowels.

Charcoal powder has been for a long period a favourite remedy in America, the Indies, and in many parts of Europe, for dysentery ; and it is extensively used, with the greatest success, on the Continent, as a remedy for nervous dyspepsia and other painful disorders of the stomach and bowels. It promotes digestion, and prevents flatus from over-distending the stomach ; thus affording a weak stomach every chance of recovering a healthy tone and action.

"In nervous affections of the stomach and bowels ; in those complaints which are so prevalent, and attended with so much pain and inconvenience, but which do not confine the sufferers to their bed, such as weight and uneasiness after eating, nervousness from laborious digestion, dyspepsia, pain in the chest, waterbrash, &c. ; for each of these disorders, the powder of charcoal is the most effectual in relieving pain, restoring the digestive powers, improving the appetite, and enabling the stomach to bear food."—Dr Belloc, Surgeon-Major in the French Army.

"The medicinal value of prepared wood charcoal (*Carbo Ligni*) was fully ascertained by army and medical officers during the last war, in the Mediterranean and the West Indies. It proved a valuable remedy in dyspepsia, intermittent and remittent fevers, acute dysentery and diarrhœa ; and as the organs and membranous tissues affected in the two last-named diseases are the same which cholera attacks, it may be inferred from analogy that charcoal will be beneficial in that most formidable malady."—Extract from Dr Borland, Inspector of Hospitals, Letter to the Board of Health.

Dr Borland further states, "that many persons not positively valetudinary, nor foregoing their ordinary occupations, but suffering annoyance from indigestion, flatulence, nausea, unpleasant taste in the palate, and offensive odour in the breath, have, to his knowledge, been entirely relieved from all these gastric evils, by the use of small doses of charcoal powder."

"In the bowel disorders of children, as well as in the ordinary weak digestion of adults, the use of charcoal powder as a prophylactic has been found of signal efficacy. Biscuits containing charcoal powder, in suitable proportion, have been found to relieve indigestion, flatulence, nausea, oppressed breathing, and irregular bowels, in a very effectual manner."—Mr Bird's 'Treatise on the Medical and Economic Properties of Vegetable Charcoal.'

Charcoal can be made of various degrees of purity, from a variety of substances, and are called either animal or vegetable charcoal, as the case may be. Animal charcoal is prepared in cast-iron cylinders ; it contains from 20 to 25 per cent. of carbon only, and is a valuable decoloriser. Vegetable charcoal is very various in its relative virtues, as the woods and vegetable substances from which it is prepared vary both in kind and quality.

Some vegetable substances contain less than 75 per cent. of carbon, the remaining 25 per cent. consisting of earthy mineral and deleterious matter. Charcoal possesses the property of absorbing noxious gases. M. Lowitz, a German chemist, about the year 1789, first applied this substance for deodorisation and purification. M. Theodore de Saussure, by a series of experiments, proved its power of altering the character of foul gases, by its peculiar properties.

Mr Turnbull, of Glasgow, in experimenting on the qualities of manure, covered 350 dead horses with charcoal, and no unpleasant odour was emitted from them.

The Irish Amelioration Society in London import peat-charcoal for agricultural purposes, and we believe it to be one of the best manures used for fertilising and invigorating the soil. As a deodorising and disinfecting agent, charcoal is now extensively employed. Of its anti-putrescent properties we give the following experiment by Mr Turnbull, who placed the body of a dog in a wooden box, for more than six months, in which he put a layer of charcoal, and covered it over with another layer, of a few inches in depth. The box was left uncovered in his laboratory, from which no offensive smell was ever discovered.

The property of charcoal to restore sweetness to tainted meat was shown by Lowitz, when in St Petersburg, in 1786.

Charcoal ventilators are used at Guildhall and the Mansion-house, for the purpose of purifying the atmosphere in those places. It has been recommended to the Board of Health, for the purification of the Thames, but without success. It is adopted in the manufacture of respirators, and, we believe, very wisely.—'The Chemist and Druggist.'

SIR HENRY MARSH, BART., M.D.

It becomes our most painful duty to record the death of Sir Henry Marsh, who expired on the 1st inst., at his residence in Merrion square, after a brief illness of about three hours' duration.

Sir Henry Marsh, having been educated in Trinity College, Dublin, where he graduated in both Arts and Medicine, was appointed Assistant-Physician, under his friend and relative, the late Dr John Crampton, to Steevens' Hospital, where he soon exhibited all the qualities essential to a successful Physician. In the year 1827, Sir Henry was elected Professor of the Theory and Practice of Medicine in the School of the Royal College of Surgeons, Ireland, which chair he filled with the greatest ability until his increasing private practice obliged him to resign it in 1832. He often stated to his medical friends that to his Professorship in the College of Surgeons he owed much of his success in after life. On the death of Dr Cheyne, Sir Henry (then Dr Marsh), a comparatively young man, took the lead amongst the many other distinguished Dublin Physicians of the day—a position which he held to the hour of his death. In 1839, Sir Henry became a Fellow of the King and Queen's College of Physicians ; and in 1840, a M.D. of the University of Dublin. In 1837 he obtained the honorary appointment of Physician in Ordinary to the Queen in Ireland. In 1839 he was created a Baronet. Sir Henry was more than once chosen President of the King and Queen's College of Physicians. He was Consulting Physician to the City of Dublin, St. Vincent's, and the Rotunda Hospitals, and to the Institution for Diseases of Children (founded by Sir Henry Marsh and Dr Charles Johnson).

As a clinical teacher, Sir Henry Marsh was unrivalled. As an author, his essays, in the 'Dublin Hospital Reports, Dublin Journal of Medical Science, &c.,' prove that he was an original thinker as well as a graphic writer. Up to a few hours before death removed him from amongst us, Sir Henry was actively engaged in correcting the sheets of his forthcoming psychological work, which has been announced by his publisher for the 1st of the ensuing year.

The Medical Profession, more especially the junior members of it, will long recollect Sir Henry Marsh as a most accomplished and painstaking Physician, who often came to their assistance, not only in the diagnosis, but likewise in the treatment of disease, both medical and dietetic.—'Dublin Medical Press.'

DEATHS.

Adams.—December 2, at Edinburgh, Alexander Maxwell Adams, M.D.

Atkinson.—November 26, at Dublin, Thomas J. Atkinson, Surgeon 31st Regiment, aged 33.

Barclay.—November 29, at Charlton, Kent, John Barclay, Surgeon R.N., aged 37.

Carbery.—September 24, at Carosal, William Declan Carbery, L.R.C.S. Irel., Assistant-Surgeon 3rd West India Regiment.

Eccles.—November 27, at Cheadle, Staffordshire, John Eccles, M.D. Univ. Edin. 1815.

Hoffman.—Recently, John Hoffman, M.D., Staff-Surgeon.

Marsh.—December 1, suddenly, at Merrion square, Dublin, Sir Henry Marsh, Bart., Fell. K.Q.C.P. Irel., M.D. Univ. Trin. Coll. Dub., one of the Physicians in Ordinary to the Queen in Ireland.

Myers.—November 28, Henry Myers, L.S.A. Lond., aged 50.

PURNELL.—November 25, suddenly, at Blackheath, William Anthony Purnell, late Physician-General of the Bombay Army.

SANKEY.—November 25, William S. Villiers Sankey, M.A. Dub. and Camb., aged 67.

SLIGHT.—November 25, Henry Slight, of Portsea, Hants, M.R.C.S. Eng., and L.S.A. Lond., 1819.

SLOAN.—November 27, John Sloan, of Kilmaurs, Ayrshire, L.F.P.S. Glasg., aged 70.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, the 29th ult. :—Frederick Favson Lee, Salisbury ; John Lovegrove, Sotwell Farm, near Wallingford, Berks ; Edward Parson, Cutcase, near Liskeard, Cornwall ; Arthur Edwin Hutchinson Trotter, Stockton-on-Tees. The following gentlemen also on the same day passed their First Examination :—William Goldsmid A'Beckett, University College ; Henry Finch, University College. As an Assistant—William Edward Porter, Melbourne House, Droitwich road, Worcester.

APPOINTMENTS.—Mr W. G. Church, of University College, Oxford, has been appointed to the office of Lee's Reader in Anatomy, vacant by the resignation of Dr Rolleston (now Linacre Professor). Mr Church obtained a first-class in Natural Science at the Easter Examination of the present year. Dr Anstie has been appointed Lecturer on Toxicology at the Westminster Hospital. Edward Liveing, Esq., M.B., Cantab., M.R.C.P., M.R.C.S., has been appointed Assistant-Physician to King's College Hospital.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting, held on Monday, December 3, Sir Charles Hamilton Bart, C.B., in the chair, the Rev. Alexander Denny, M.A., and Edward Smaith, Esq., were *elected* Members of the Royal Institution ; and Carl Haag was *admitted* a Member.—Henry Bence Jones, M.D., F.R.S., was elected Secretary of the Royal Institution, in the room of the Rev. John Barlow, M.A., F.R.S., resigned, who was elected a Manager. The following arrangements for the Lectures before Easter, 1861, were announced :—Six Lectures on the Chemical History of a Candle (adapted to a Juvenile Auditory)—by Michael Faraday, Esq., D.C.L., F.R.S., &c., Fullerian Professor of Chemistry, R.I. Twelve Lectures on Fishes—by Richard Owen, Esq., D.C.L., F.R.S., Fullerian Professor of Natural Physiology, R.I. Twelve Lectures on Electricity—by John Tyndall, Esq., F.R.S., Professor of Natural Philosophy, R.I. Ten Lectures on Inorganic Chemistry—by Dr Edward Frankland, Esq., F.R.S., Lecturer on Chemistry at St Bartholomew's Hospital.

THE ROYAL SOCIETY.—The anniversary meeting of this Society was held recently, General Sabine, Treasurer and Vice-President, in the chair. The anniversary address was delivered, after which the medals were presented as follows : —The Copley Medal, to Professor Robert Wilhelm Bunsen, of Heidelberg, Foreign Member of the Royal Society, for his "Researches on Cacodyl, Gaseous Analysis, the Volcanic Phenomena of Iceland, and other Researches ;" a Royal Medal to Mr William Fairbairn, F.R.S., for his various "Experimental Inquiries on the Properties of the Materials employed in Mechanical Construction ;" a Royal Medal to Dr Augustus Waller, F.R.S., for his "Investigations into the Anatomy and Physiology of the Nervous System, and for the Introduction of a valuable Method of Conducting such Investigations ;" and the Rumford Medal, to Professor James Clerk Maxwell, for his "Researches on the Composition of Colours, and other Optical Papers." The Society then proceeded to the election of Council and Officers for the ensuing year. The following gentlemen were declared duly elected :—President, Sir Benjamin Collins Brodie, D.C.L. ; Treasurer, Major-General Edward Sabine, R.A., D.C.L. ; Secretaries, William Sharpey, M.D., LL.D., and Mr George Gabriel Stokes, M.A., D.C.L. ; Foreign Secretary, Mr William Hallows Miller, M.A. : other Members of the Council, Mr. John Couch Adams, Sir John Peter Boileau, Mr Arthur Cayley, Mr William Fairbairn ; Hugh Falconer, M.D. ; William Farr, M.D., D.C.L. ; Mr Thomas Graham, M.A., D.C.L. ; Sir H. Holland, M.D. ; D.C.L. ; Mr Thomas Henry Huxley ; Sir J. G. Shaw Lefevre, M.A., D.C.L. ; Mr James Paget ; Mr Joseph Prestwich ; Mr William Spottiswoode, M.A. ; Mr John Tyndall, Ph.D. ; Alexander William Williamson, Ph.D. ; Colonel Philip Yorke. After the election, the Fellows and their friends dined together at the Thatched-House, General Sabine occupying the chair.

ROYAL COLLEGE OF SURGEONS.—Notice has been given that the next Examininations of Candidates for the title of M.R.C.S. will be held as follows :—The Primary, or Anatomical Examination, on January 19, and following days ; and the Pass, or Surgical Examination, on January 26, and following days. Examinations of candidates under the old regulations will be held at intervals in the mean time, as usual.

UNIVERSITY OF LONDON.—The following are lists of Candidates who have recently passed the respective examinations indicated :—SECOND M.B. EXAMINATION, 1860.—EXAMINATION FOR HONOURS.—*Physiology and Comparative Anatomy.* —John Easton (University Scholarship and gold medal), King's College ; John Harley (gold medal), King's College ; and Frederick Poynton Weaver, Liverpool Infirmary and Guy's Hospital. *Surgery.* —C. J. Bracey (University Scholarship and gold medal), Queen's, Birmingham, and King's Colleges ; Thomas Hiron Bartleet (gold medal), Queen's, Birmingham, and King's Colleges ; James Braithwaite, Leeds School of Medicine and Guy's Hospital ; John Easton and John Harley, King's College, equal ; Charles Grabham, St Thomas's Hospital. *Medicine.*—Eustace Smith (University scholarship and gold medal), University College ; John Harley (gold medal), King's College ; Thomas Hiron Bartleet and Charles James Bracey, Queen's, Birmingham, and King's College, equal ; Henry Forbes Winslow, King's College ; Edward Woakes, St Thomas's Hospital. *Midwifery.*—John Easton (gold medal), King's College ; Charles James Bracey, Queen's, Birmingham, and King's Colleges, and Washington Lafayette Winterbotham, University College, equal ; William Caley, King's College ; James Braithwaite, Leeds School of Medicine and Guy's Hospital, and John Harley, King's College, equal ; Henry Forbes Winslow, King's College ; Frederick Poynton Weaver, Liverpool Infirmary and Guy's Hospital. *M.D. Examination*, 1860.—John Henry Bartlet, University College ; Rayner Winterbotham Batten, St Bartholomew's Hospital ; Francis Thomas Bond, B.A., Queen's College, Birmingham ; William Henry Broadhent, Royal Manchester and St Mary's Colleges ; Thomas Buzzard, King's College ; Thomas Armstrong Cammack, University College ; Richard Hunt, Guy's Hospital ; Philip Sydney Jones, University College, Edmund Symes Thompson, King's College.

PATHOLOGICAL SOCIETY OF DUBLIN.—The first meeting of the Society for the Session 1860-61 was held in the Anatomical Theatre of Trinity College, on Saturday, November 24, when the following Officers and Council were elected for the year ending November, 1861 :—President : Christopher Fleming. Vice-Presidents : Joseph O'Ferrall, Benjamin G. M'Dowel, Fleetwood Churchill, Samuel Gordon, James S. Hughes, Alfred H. M'Clintock. Council : Robert Adams, John Banks, Thomas Beatty, Dominick J. Corrigan, John Hamilton, Edward Hutton, Robert Law, Cathcart Lees, Sir Henry Marsh, Bart. (since deceased), Robert Mayne, Josiah Smyly, Joliffe Tufnell. Honorary Secretary : William Stokes. Secretary and Treasurer : Robert W. Smith. Secretary for Foreign Correspondence : Robert D. Lyons. The subject selected for the Society's gold medal, to be adjudicated at the close of the session to the best essayist, is, "The Diagnosis and Pathology of Diseases of the Spermatic Cord, and of the Testicle and its Coverings." In consequence of the lamented death of Sir Henry Marsh, Bart., one of the Council, the second meeting, intended to have been held on the 1st inst., did not take place.

ROYAL MEDICAL SOCIETY OF EDINBURGH.—The following gentlemen have been elected office-bearers in this venerable Society for the ensuing year, being its 124th Session :—Presidents, Mr J. Crichton Browne, Mr Alexander Crum Brown, M.A., B. Sc. (Lond.), Mr William Watson, Mr James Pettigrew ; Treasurer, Mr J. F. Macfarlan ; Honorary Secretaries, Mr Thomas R. Fraser, Mr John Duncan, M.A. ; Curator of Library, Mr R. J. B. Cunynghame ; Sub-Librarian, Mr W. Thomson.

MEDICAL PRACTITIONERS IN PRUSSIA.—At the end of 1859 there were for the entire Prussian Kingdom, 1 Physician to 4099 inhabitants, 1 Surgeon (an inferior Practitioner) to 10,823, 1 Apothecary to 11,602, and 1 Midwife to 1554 inhabitants. Of course the proportion differs in different parts of the kingdom, and in the capital is as follows :—1 Physician to 953 inhabitants, 1 Surgeon to 4477, 1 Apothecary to 11,710, and 1 Midwife to 3108.—'Berlin Med. Zeit.,' No. 45.

THE ANTI-TOBACCO MOVEMENT.—A meeting for the promotion of the objects of the British Anti-Tobacco Society was held in Edinburgh last week. Professor Miller moved the first resolution :—"That as the constituent principles which tobacco contains are highly poisonous, the practice of smoking and snuffing tends in a variety of ways to injure the physical and mental constitution." He said, no man who was a hard smoker had a steady hand. But not only had it a debilitating and paralysing effect ; but he could tell of patients who were completely paralysed in their limbs by inveterate smoking. He might tell of a patient of his who brought on an attack of paralysis by smoking ; who was cured, indeed, by simple means enough, accompanied with the complete discontinuance of the practice ; but who afterwards took to it again, and got a new attack of paralysis ; and who could now play with himself, as it were, because when he wanted a day's paralysis, or an approach to it, he had nothing to do but to indulge more or less freely in the weed. Only the other day, the French—among whom the practice was carried even to a greater extent than with us —made an estimate of its effects in their schools, academies, and colleges. They took the young men attending these institutions, classified them into those who smoked habitually and those who did not, and estimated their physical and intellectual standing,—perhaps their moral standing too, but he could not say. The result was that they found that those who did not smoke were the stronger lads and the better scholars, were altogether more reputable people and more useful members of society than those who habitually used the drug. What was the consequence ? Louis Napoleon—one of the good things which he had done—instantly issued an edict that no smoking should be permitted in any school, college, or academy. In one day he put out about 30,000 pipes in Paris alone. Let our young readers put that in their pipes and smoke it !—Mr Reynolds seconded the resolution, which was agreed to. Mr Thomas Knox stated that the present was only the initiatory meeting of a series which it was intended to hold in Edinburgh to promote the movement. He moved—"That as smoking has a tendency to encourage the drinking usages of society, not only by creating morbid thirst, but also by its exhausting power, thereby inducing recourse to a falsely supposed substitute, it is greatly calculated to foster crime and dissipation in the masses." This and other similar resolutions were unanimously passed.

ACTION OF CARMINE ON ORGANIC CELLS.—In a paper to be found in 'Canstatt's Jahresbericht,' 1858, vol. i., p. 202, Wittich confirms the conclusions drawn by Gerlach from his experiments (communicated by him during the Meeting of Naturalists at Bonn) upon the action of pigments, and especially of a solution of carmine when brought into contact with dead organic cells, and other elementary forms of cell origin. As soon as the coloured solution is brought into contact with cell-structure, the nuclei become coloured, the other portions of the cell, colourless at first, only exhibiting the colour after a longer imbibition. The elementary forms of tissue originating in cells comport themselves as do the nuclei, attracting to themselves the colouring matter. Thus in connective tissue it is only the cells, and especially their nuclei, which are coloured, while the intervening connective substance remains uncoloured. The muscular fibres appear coloured along their entire length. Of the nervous tissues, the ganglionary cells, and especially their nuclei, are of an intense red. In the non-sympathetic nervous fibres, the medullary substance, and especially the axis cylinders, are coloured, while the neurilemma remains colourless. In the vascular structures the cells and their nuclei are coloured in the tunica intima, while the elastic fibres of the tunica media remain colourless ; the muscular fibres are coloured, as are the cells of the connective substance of the tunica adventitia—the other portions remaining uninfluenced. In his experiments with colouring matters, Gerlach placed thin slices of brain which had been hardened by chromate of potash for two or three days in a mixture of one ounce of water, and two or three drops of a concentrated solution of carminate of ammonia. V. Hessling, the reporter in Canstatt, observes that there is nothing new in Gerlach's statements, every histologist familiar with injections being aware of the facts he states. V. Hessling himself described them in the 'Illustr. Med. Zeitung,' Theil 1., seven years ago.

FINSBURY DISPENSARY.—The office of Physician to the Finsbury Dispensary being vacant by the resignation of Dr Thomson, the election of a successor is announced for the 17th inst. This is one of the few institutions at which the services of the medical attendants receive an acknowledgment, amounting ere to 40*l.* annually.

APPOINTMENTS FOR THE WEEK.

Wednesday, December 12.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

HUNTERIAN SOCIETY.—Council Meeting, 7½ p.m.—Dr Daldy, "On Cases of Hemiplegia, without Structural Lesion," 8 p.m.

NORTH LONDON MEDICAL SOCIETY.—Dr Hillier, "On Two Cases of Diphtheria, in which laryngotomy was performed," 8 p.m.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—Prof. Leone Levi, "On Italian Commerce and Industries," 8 p.m.

Thursday, December 13.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Surgical Home.—2 p.m.

KING'S COLLEGE MEDICAL SOCIETY.—Dr Duffin, "On Perforations of the Peritoneum."

Friday, December 14.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, December 15.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—Clinical Lecture on "Epilepsy and Paralysis," by Dr Brown-Séquard, 3½ p.m.

Monday, December 17.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.

MEDICAL SOCIETY OF LONDON.—8½ p.m.

Tuesday, December 18.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

On Diphtheria. By Edw. H. Greenhow, M.D. London: John W. Parker and Son, West Strand.

Introductory Addresses at the Ledwich School of Medicine. By J. H. Warton, F.R.C.S.I., Dublin.

NOTICES TO CORRESPONDENTS.

Mr H. BAKER.—It is immaterial; the power exists, but can never be enforced.

Dr PHILLIPS.—Yes.

A PHARMACEUTIST calls our attention to the unintelligible scrawls in which physicians delight to write their prescriptions, and points out the danger to life that necessarily attends such a practice. He urges that, as one method of abating the evill, all prescriptions should be written in full, and in English. He observes that the chemical nomenclature now in use would be a sufficient blind to the curiosity of the public. These observations deserve consideration. There are already some physicians who write in English, and we should be glad to see the practice general. Whatever conduces to the safety of life should be more valued than an antiquarian adherence to conventional usages.

M.R.C.S. ENG. & L.A.C.—1st. Yes.—2nd. Dr Todd laid it down as an axiom, that *always* when there is a tendency to delirium in rheumatic fever, stimulants should be administered.—3rd. It is a matter of opinion.

MEDICUS (Ramsgate) is thanked.

I. O.—The proper parties to whom to apply are the Local Board of Health, or other local body acting in that capacity.

A SUBSCRIBER.—We think C.'s conduct, under the circumstances, highly discourteous; but it is one of those breaches of good manners that it is wiser to overlook, and pleasanter to forget.

Mr COX.—The Publisher will attend to it.

Mr IRVINO.—No.

A POOR-LAW SURGEON.—1st. Correct.—2nd. No.—3rd. We are unable to say.

Mr FLOWER.—Received and inserted.

Dr GASON'S communication on the Cholera in Tuscany, received. His requests shall be attended to.

H. B. S.—We cannot comply with your request, not having the agency necessary for the purpose.

CHIRURGUS.—Yes; under the new Act.

A METROPOLITAN POOR-LAW SURGEON.—It is not our province to express a positive opinion as adverse to the ruling of one of Her Majesty's Judges; but still we cannot believe that Chief-Justice Erle was right in stating that no lunatic can be confined unless proved to be "dangerous." We have commented upon the trial elsewhere. Dr Clarke has been, in our judgment, harshly treated. The girl was not sent to an asylum,—perhaps she ought to have been. That women may be insane to-day and sane to-morrow, is a matter of common experience. We have known many instances of women continuing in a state of lunacy for several days, and even weeks, and yet were no sooner placed under proper surveillance, away from the irritating influences of old associations, than they almost immediately recovered their sanity. The opinion of even an alienist is of no value in such circumstances, as against that of the Medical Attendant who had an opportunity of observing the case before removal.

Mr B. PHILLIPS is thanked.

A SUBSCRIBER.—The perchloride of iron is the best styptic: long-continued pressure is efficacious Awhere it can be applied.

"DOCTOR."—Received; you are right.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

32 SOHO SQUARE, LONDON, W.
October 22nd, 1860.

Notice.—The Copy of the MEDICAL REGISTER to be printed and published in 1861, as directed by the 27th Section of the Act, will contain those Names only which appear on the General Register as existing on the last day of January, 1861.

It is particularly requested that claims for the Registration of first or additional Qualifications, and Notices of Alteration of Residence, may be sent to this Office as soon as possible.

Flour — (Essex) — Warranted free from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs), 11s.; Households (recommended for bread-making), 10s. 4d.; Seconds, 9s. 8d.; Wheat Meal for brown bread, 9s. 8d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill, Witham, Essex, or 97 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half-sack delivered free to any rail station 200 miles. German Yeast.

Antimargaric Cod-liver Oil, OR COD-LIVER OLEIN,
Extracted by Messrs. WILLIAM and EBENEZER ROTTON, 112 Dale End, Birmingham, and at their Fisheries, Scotland.

Wholesale Agent—Mr J. W. N. BREWER, Pharmaceutical Chemist, 5 Liverpool street, Old Broad street, E.C., London.

This preparation is strongly recommended as containing all the active principles of Cod-liver Oil without its impurities. Olein will be found to agree with the most delicate stomach; and in those cases in which pain, nausea, or eructations are produced by the Oil, the Olein is an invaluable substitute. In order to prove its superiority over every other, it has been subjected to the most scientific analysis, as proved by testimonials received from the well-known Professors of Chemistry and Therapeutics, Wm. Herapath, F.C.S., etc. etc., Old Park, Bristol; Septimus Gibbin, A.B. and M.B. Cantab., 3 Finsbury square, London; John Postgate, A.C. and M.D.; Bell Fletcher, M.D., etc. etc.; D. W. Crompton, M.D., etc. etc.; Sands Cox, M.R.C.S., Senior Surgeon to the Queen's Hospital, Birmingham, etc. etc.

Pint Bottles, 2s. 6d.; half-pints, 1s. 3d.; quarter-pints, 8d.

CAUTION.—In order to secure the genuine Cod-liver Olein, be particular in the address, 112 Dale End, Birmingham (the original Establishment), having no connection with any other. None is Genuine unless Capsuled and Signed "WILLIAM and EBENEZER ROTTON."

Letts's Medical Diary, NOTICE arranged for Vaccinations, Accouchments, Nurses' Addresses, &c., Patients' Names with column for Daily Visits. Neatly bound in cloth, pocket book, flap, pencil, and clasp, 2s.; French Morocco Tuck, two pockets and pencil, gilt edges, 3s.; best Morocco or Russia Pocket Book, 10s. 6d.; with divisions for instruments, 17s. and 15s. (Double the substance, 1s. 6d. extra.) Instrument Cases for ditto, 4s. 6d.

The other Editions of LETTS'S DIARIES commonly used by MEDICAL MEN, are Nos. 1, 2, 5, 9, 10, 12, 14; the Professional Appointment Diary; the Monthly Professional Diaries; Medical Visiting Lists, etc.

LETTS'S READING EASEL for INVALIDS, from 20s. to 40s. Sold by all Booksellers.—Fully descriptive catalogues gratis.

LETTS, SON, and Co., STATIONERS, 8 Royal Exchange, London, E.C.

Washing, Drying, & Mangling Machines.
Williamson's Patent MACHINES are in use at numerous Public Establishments.—Can be seen in operation (daily) at WILLIAMSON'S, Patentee and Manufacturer, 133 HIGH HOLBORN.—Illustrated Lists free by post.

Jones's Flesh Soap, for the TOILET or NURSERY, One Shilling the Packet. Most beneficial for producing a CLEAR, SOFT, and HEALTHY SKIN. To be had of

STEPHEN JONES (late W. Jones and Sons),
Old Established Candle, Soap, and Italian Warehouse, Near the Turnpike, Islington.
Established 1794.

TEETH WITHOUT SPRINGS,

BY HER MAJESTY'S ROYAL LETTERS PATENT.

Newly-invented Application of PREPARED INDIA-RUBBER in the construction of Artificial Teeth, Gums, and Palates.

MR EPHRAIM MOSELY,
SURGEON-DENTIST, 9 GROSVENOR STREET,
SOLE INVENTOR AND PATENTEE.

A new, original, and invaluable invention, consisting in the adaption, with the most absolute perfection and success, of CHEMICALLY-PREPARED INDIA-RUBBER, in lieu of the gold or bone frame. The extraordinary results of this application may be briefly noted in a few of their most prominent features:—All sharp edges are avoided; no springs, wires, or fastenings, are required; a greatly-increased freedom of suction is supplied; a natural elasticity, hitherto wholly unattainable, and a fit perfected with the most unerring accuracy, are secured; while, from the softness and flexibility of the agent employed, the greatest support is given to the adjoining teeth when loose, or rendered tender by the absorption of the gums. The acids of the mouth exert no agency on the Chemically-prepared India-rubber, and as it is a non-conductor, fluids of any temperature may be retained in the mouth, all unpleasantness of smell or taste being at the same time wholly provided against by the peculiar nature of its preparation. Teeth filled with gold, and Mr Ephraim Mosely's Cement, the only stopping that will not become discoloured, particularly recommended for front teeth.—9 Grosvenor street (W), London; 14 Gay street, Bath; 10 Eldon square, Newcastle-on-Tyne.

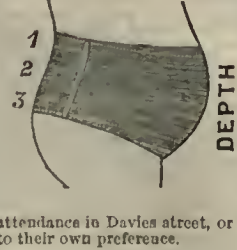
The London Home for SURGICAL DISEASES OF WOMEN, 16 Stanley Terrace, Notting Hill.—This Hospital is established for the treatment of surgical diseases peculiar to women, and combines the organisation of a hospital with the comforts of a home.

A weekly payment, regulated by circumstances, and varying from 10s. to 40s., must be made by each patient or her friends towards the household expenses, except in the case of those specially recommended by Life Governors.

There are 20 beds, 16 of which are appropriated on the above scale of payments to females of a better class than ordinary hospital patients; and four are reserved for poor patients recommended by Life Governors.

Donations and subscriptions are earnestly solicited, and may be paid to the Treasurer, R. Ruthven Pym, Esq., at the Western Branch of the Bank of England, Burlington gardens; and to the Hon. Secretary, or Lady Superintendent, at the Home. GEORGE FORBES, Hon. Sec.

Mr P. Bourjeaurd's Registered Spiral Elastic Compressional BANDAGES, to be obtained only at No. 11 DAVIES STREET, BERKELEY SQUARE, W., and No. 11 RUE DES BEAUX-ARTS, PARIS; and through the Profession.



Mr PHILIP BOURJEAURD, in submitting the accompanying diagrams, presents his best thanks to those Gentlemen who have, for some years past, prescribed his appliances in all cases indicating their necessity, and begs respectfully to assure others, who have not used them in their practice, that they will find them a most valuable assistance in most cases indicating the necessity of compression or support. The inventions consist of Abdominal Supporters, Hernia Apparatuses, Ankle, Knee and other Bandages, with various other Appliances, that the élite of the Profession have pronounced to be most ingenious.

N.B.—No. 11 DAVIES STREET, BERKELEY SQUARE, W., near Mivart's Hotel. The establishment is strictly private, not having any show of Bandages in the window. A highly-respectable married female to wait upon Ladies, who may insure her attendance in Davies street, or at their own establishments, by favouring Mr Bourjeaurd with instructions, according to their own preference.

AT HOME FROM TEN TILL SIX.

Classical and Mathematical.

—Dr STEGGALL (assisted by the Rev. L. J. Lovekin and T. Hogan, Esq., M.A.) Prepares Gentlemen for their Examinations at the following Boards:—Matriculation Examination of the London University; Preliminary Examination at Apothecaries' Hall; Fellowship Examination at the Royal College of Surgeons; Preliminary Examination at the Royal College of Surgeons.—For terms, &c., apply to Dr STEGGALL, before 1 and after 3 o'clock daily, at 2 Southampton street, Bloomsbury square.

N.B.—No Vacation during the Summer months.

Evening Demonstrations of

ANATOMY. — Mr CHRISTOPHER HEATH, Demonstrator of Anatomy at the Westminster Hospital, will continue his Evening Course of DEMONSTRATIONS and EXAMINATIONS upon the DISSECTED SUBJECT on Wednesday, during the Winter Session. The Demonstrations take place on Monday, Wednesday, and Friday evenings, during the Winter Session, from Seven to Nine o'clock, at the Westminster Hospital. Entrance fee (perpetual) Five Guineas.

Mr Geo. Hind continues

his DEMONSTRATIONS and EXAMINATIONS, commencing on the 15th of September, at 29 Newman street, Oxford street.

Hours, from Ten to Twelve a.m., and Six to Eight p.m.

CHLORODYNE.

J. T. Davenport begs to

direct attention to the disgraceful and fraudulent practice of certain parties who apply the term "CHLORODYNE" to compounds of THEIR OWN MANUFACTURE, WELL KNOWING that the word is SPECIFICALLY applied to a remedy SOLELY DISCOVERED and INTRODUCED by Dr J. COLLIS BROWNE, M.R.C.S.L. (late Army Medical Staff), the formula of which is confided to J. T. DAVENPORT, and NONE other;—hence the assumption of the title, claim to discovery, or manufacture of CHLORODYNE by any other persons is a direct palpable deceit and imposition.

The Medical Testimony published on the extraordinary properties of this remedy is exclusively applied to

Dr J. COLLIS BROWNE'S CHLORODYNE.

WHOLESALE DEPOT,

33 Great Russell street, Bloomsbury square, London.

Millikin, late Bigg and Millikin,

Surgical Instrument Maker and Anatomical Machinist to Guy's and St Thomas's Hospital, No. 0 St Thomas's street Southwark S.E.

Medical Fixture and Glass

WAREHOUSE. — W. HAY, 25 Little Queen street, Lincoln's inn fields, begs to inform the Profession that he Fits-up every description of Medical Shops and Surgeries, and has in Stock a large assortment of New and Second-hand Drawers, Counters, Desks, Dispensing Screens, Bottles, Jars, and every requisite for the above.—A large assortment of Medical Lamps.

Loan, Discount, and Deposit

BANK.

Established 1849.—145 Blackfriars road, S.

DEPOSITS.—Sums of £1 and upwards received, bearing interest at from 5 to 10 per cent., withdrawable as per agreement.

DISCOUNT.—Approved Trade Bills negotiated at two days' notice.

LOANS.—From £6 to £200, repayable by easy instalments, on approved Personal Security, Bills of Sale, Mortgages, Life Policies or otherwise.

Prospectuses, and every Information, may be obtained by letter or personal application.

EDWARD LEWIS, Manager.

145 BLACKFRIARS ROAD, S.

Liquor Castanea Equina.—

Messrs. REW and Co. respectfully solicit the attention of the Profession to this Preparation of the Horse-Chesnut; taken internally for Rheumatic Gout and Rheumatism, it is a safe, agreeable, and most efficacious remedy.

Dose, two to four drachms. Price 12s. per pound.

The Oil of Horse-Chesnuts applied externally for enlarged and stiff joints, acute or inflammatory pain of any kind, gives almost immediate relief.

These genuine Preparations of the Horse-Chesnut are prepared only by REW and CO.

LITHIA WATER, LITHIA POTASH, and LITHIA AMMONIA WATER. These Waters are prepared according to the Instructions of Dr Garrod, and each bottle is guaranteed to contain the proper proportion of Lithia. 5s. per doz.

R. M. REW and CO., Operative Chemists, 282 Regent street, London.

TO SURGEONS, DENTISTS, &c.

The Best House in London

for SECOND-HAND INSTRUMENTS is Mr WM. LAWLEY'S, Lombard House, 73 Farringdon street, City.

Established upwards of a century.

A first-class full SURGEON'S ARMY CASE for Sale.

N.B. The largest stock of Second-hand Dissecting Cases in London. Also, A great variety of New and Second-hand Army and Navy Regulation Cases.

Instruments Bought, Sold, or Exchanged.

PULVIS JACOBI *VER.*, NEWBERY'S.

To the Medical Profession of Great Britain and Ireland.

GENTLEMEN,—We beg to call your attention to the following extract from a Paper by the late John Cheyne, M.D., F.R.S.E., M.R.I.A., Physician to the Hardwicke Fever Hospital, Dublin, and Physician-General to His late Majesty's Forces in Ireland, &c., &c., contained in "*the Dublin Hospital Reports*," *vol. i, p.* 320.

"The following very simple method of "exhibiting JAMES'S POWDER, in cases "of undue determination of blood to the head, "is that which I have generally pursued. The "patient is made to begin with a very moderate "dose, not more than two grains at bedtime, "and to increase the dose by half-a-grain every "night, until some sensible effect is produced "upon the stomach, bowels, or skin. Should "the stomach be affected with sickness, the dose "must be lessened, by one grain on the following "night. *By the addition of a little rhubarb "to it, a larger quantity of* JAMES'S "POWDER *may be administered than the "stomach could otherwise bear.* If the skin "is softened, or the bowels affected, the dose "should not further be increased, but it must be "repeated every night for a considerable length "of time: in several instances I have known "eighteen or twenty grains taken for a consi-"derable period without any inconvenience."

To secure the dispensing of the *original* preparation, which, for 114 years, has been sold by the house of Newbery and Sons, in St. Paul's Churchyard, it is necessary to prescribe it as "PULVIS JACOBI VER., NEWBERY'S," otherwise another article (wanting in the best properties, and recommended to be given in a different code of dose, *though called by the same name*) may be substituted for the original medicine.

This substitution must bring disappointment, and of course lead Practitioners to give up prescribing Dr. James's Powder altogether, or to regard it as a preparation on which no dependance can be placed.

FRANCIS NEWBERY AND SONS.
45, St. Paul's Churchyard, London.

Prices for Dispensing ½ oz. Bottle 3*s.* 4*d.*, 1 oz. 9*s.* Usual Discount to the Profession.

James's Fever Powder.

4s. 6d. per bottle; packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31 Hunter street, Brunswick square, London.

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all Wholesale Druggists.

PULVERMACHER'S PATENT

GALVANIC ANTI RHEUMATIC CHAIN BANDS.

Unequalled as are the effects of the Chain-Bands in all kinds of Rheumatic Pains, Gout, Neuralgia, Indigestion, Epilepsy, and Female Complaints, still more extraordinary is the relief they afford in Sciatica, Lumbago, Head, Ear, and Tooth-ache, Bronchitis, Urinary Disorders, and all those Maladies attendant on Debility and Loss of Nervous Functional Force, &c. Persons interested in this Invention can convince themselves of the efficiency and certainty of the curative power of the Chain-Bands, by perusing the Book,

PULVERMACHER'S MEDICO-GALVANIC IMPROVED SYSTEM,

containing extracts from the learned Works of Physicians, Physiologists, and Philosophers, marked with the pages from whence they are taken; numerous private Testimonials of a most interesting character, with Reports of wonderful Cures from the Hospitals of England, France, Germany, and America.

The Invention is adopted by the Académie de Médecine, Paris; the Royal College of Physicians, London; and by the Imperial Faculty of Vienna. It is also distinguished by the support of Sir C. Locock, Bart., Physician to her Majesty the Queen; Professor Oppolzer, Physician to the Emperor of Austria; by Dr Rayer, Physician to Napoleon III; and others of celebrity; and was rewarded at the Great Exhibition of all Nations in 1851.

Chain-Bands, 5s., 10s. 6d., 15s., 18s., according to power.

Messrs PULVERMACHER and Co., 73 Oxford street.

Human Osteology

from France.—RAGINEL, 38 Ludgate hill, City, E.C., London. Patronised by the Royal College of Surgeons of England. Illustrated Osteology on the bones themselves. Very large stock on the lowest possible terms. Disarticulated Skulls, in twenty-two pieces, in box. All the bones of the disarticulated skulls will be fitted in right order in the presence of the purchaser, so as to show that every bone of each set belongs to the same skull; it will be the same for all other disarticulated pieces. Skulls with Sections. Hands and Feet on cat-gut. Disarticulated Skeletons, quite complete, with the Skull same body. Articulated Male Skeletons, the bones very well marked.

STUDENT'S CASE OF OSTEOLOGY, COMPLETE.

Splendid Pieces for Lecturers and Museums.

Elastic Supporting Fabrics,

of very superior textures, for Varicose Veins, Accouchement, Spinal Affections, Hernia, &c. Instructions for measurement, and prices on application to the Manufacturers, POPE and PLANTE, 4 Waterloo place, Pallmall, London, S.W.

RUPTURES. BY ROYAL LETTERS PATENT.

White's Moc-main Lever

TRUSS is allowed by upwards of 200 Medical Gentlemen to be the most effective invention in the curative treatment of HERNIA. The use of a steel spring, so often hurtful in its effects, is here avoided: a soft bandage being worn round the body, while the requisite resisting power is supplied by the MOC-MAIN PAD and PATENT LEVER, fitting with so much ease and closeness that it cannot be detected, and may be worn during sleep. A descriptive circular may be had, and the Truss (which cannot fail to fit) forwarded by post, on the circumference of the body two inches below the hips being sent to the Manufacturer,

JOHN WHITE, 228 Piccadilly, London.

Price of a Single Truss, 16s., 21s., 26s. 6d. and 31s. 6d.—Postage, 1s.

Price of a Double Truss, 31s. 6d., 42s. and 52s. 6d.—Postage, 1s. 8d.

Price of an Umbilical Truss, 42s., and 52s. 6d.

Postage, 1s. 10d.

Elastic Stockings for Vari-

COSE VEINS, and all cases of Weakness and Swelling of the Legs, Sprains, &c. They are porous, light in texture, and inexpensive, and are drawn on like an ordinary Stocking. Price 3s 6d. 7s. 6d., 10s., and 16s. each. Postage, 6d.

JOHN WHITE, MANUFACTURER,
228 Piccadilly, London.

Lateral and Angular Cur-

VATURES of the SPINE.

In calling the attention of the Profession and Public to the SUPPORTS made by them, WM. WHITING and SONS beg to state that their extensive experience (over twenty years) warrants them in asserting that the IMPROVED SUPPORT which they now manufacture will be found to be the most effectual of any in use. At the same time, they are LIGHT, COMFORTABLE TO WEAR, AND COMPLETELY INVISIBLE THROUGH THE DRESS, as experienced by the many hundreds of persons of every age and sex who are now using them.

W. W. and Sons would also invite attention to their IMPROVED EXERCISING MACHINES, SPINAL COUCHES, and their various other contrivances required in Orthopædic practice.

Manufactory, 28 High street, Camden town.

N.B.—Makers (by authority) to the Spinal Hospital, Portland road, Regent's park, founded by the late Dr Verral.

Surgical Instruments.—

J. ARNOLD continues to supply Instruments of the best workmanship at moderate prices, manufactured on the premises under his own superintendence.

J. ARNOLD, 35 and 36 West Smithfield, E.C.

Established 1819.

Chiosso's Gymnasium and

SCHOOL of ARMS, 231, EUSTON ROAD, Corner of Gower street North (near University College).

Mr ANTONIO CHIOSSO begs to draw the attention of Parents, Guardians, and all those who have the charge of Youth, to his system of Physical Education, which has proved, through experience, to be the most invaluable means of rectifying Physical Defects in the human organisation, such as Curvature of the Spine, Contraction of the Chest, general Debility of Body, &c., &c. Classes meet every hour of the day, attended personally by Mr Chiosso, from 9 A M. till 10 P.M.

Fumigations of Sulphur,

Chlorine, Mercury, and simple Hot-Air and Vapour Baths, continue to be administered at No. 40 Great Marlborough street, under the guidance of Dr GREEN, commenced in 1822, and recommended for the majority of long standing complaints.

Nervous and Mental

DISORDERS.—Wyke House, Sion hill, Isleworth, Middlesex, W.—A Private Establishment for the Cure and Residence of Ladies and Gentlemen mentally afflicted.—Proprietor, E. S. WILLETT, M.D.

CLINICAL LECTURES.

ON DISEASES OF WOMEN.

DELIVERED AT ST THOMAS'S HOSPITAL,
BY CHARLES WALLER, M.D., Obstetric Physician to the Hospital.

LECTURE V.—THE USE OF THE SPECULUM—LEUCORRHŒA.

(Continued from page 372.)

I stated in my last lecture, gentlemen, when speaking of the comparative value of the simple tubular speculum as contrasted with that of Ricord's, which is divided into several portions, that in cases where the cervix uteri is much increased in size, its entire surface cannot be easily exposed to sight by the former instrument, unless it be of very large size throughout, as there are no means of expanding it after its introduction, and hence difficulty is experienced in its application. The patient must also necessarily suffer a considerable amount of pain.

Some of you have had opportunities of seeing cases of ulcerated cervix uteri whose boundaries could not be seen without great dilatation. Now, unless the vagina be very greatly relaxed, and the genital fissure of large size, it would be impossible to introduce a tubular speculum of the required magnitude. Some time ago, a case was under my care in Elizabeth's Ward, in which the ulceration extended over the entire surface of an enlarged cervix uteri, involving also a portion of the vagina: a comparatively small portion of this would have been seen through a common tubular speculum. The other form of instrument is free from all these objections. I now show you the speculum I have used for several years past: its size is moderate; indeed, it is comparatively small—composed of four blades and a handle removeable at pleasure: it is, consequently, very portable. The four blades of which the speculum is formed are so constructed as to allow a certain degree of overlapping; they are kept firmly together by this slender stem of wood, having at one extremity a smooth wedge-like process, and at the other a handle furnished with two portions of thin steel, which together act as a spring. The round, smooth portion of wood, you will observe, projects beyond the blades; and this arrangement renders the introduction of the instrument easy to the operator, and painless to the patient. By means of the spring, the four blades are kept in close contact, so that they are compressed into a small space: by pressing the handles together, the spring acts, the wooden stem is released, and when removed altogether, the required degree of dilatation may be effected without difficulty. It is supposed by those who have had little experience in the use of the speculum, that it cannot be effectively employed without much indelicate exposure. This is a most erroneous notion: not the slightest exposure of any kind is required; and as for indelicacy, there is certainly no more in a specular than in a digital examination, and probably not so much.

Mode of introducing the Speculum.—Some of you have seen the way in which these examinations are made; but as there may be others now present who have not yet availed themselves of the opportunities afforded them in the wards of the Hospital, I shall shortly describe the *modus operandi*. The female should be placed in bed, in what is called the obstetric position—that is to say, just as if she were about to be delivered, namely, on her left side, the body slightly curved, the knees being at the same time a little bent upwards towards the abdomen, the buttocks approaching the side of the bed. A digital examination is then to be made, by passing the index finger previously anointed with unctuous substance into the vagina, and rapidly carrying it onwards until the os uteri is reached. This is found in different positions in different individuals, as regards its relation to the pelvis: it is sometimes high up, and reached with difficulty; at others, and more generally, it is low down; sometimes it is found pointing forwards, but much more frequently it will be found at the posterior part of the pelvis. The uterus should be carefully examined, whether there be any alteration in position size, &c.; whether there be pelvic tumour, inflammatory or otherwise. If this examination be satisfactory, nothing further need be attempted; if the information thus gained be insufficient, the speculum, having been previously well oiled, is to be passed up the vagina until the wooden plug at its extremity rests upon the os uteri. When this has been accomplished, the handles are to be pressed together, and the necessary degree of dilatation effected without the bed-clothes being at all raised from the body of the patient: the sheet should then be wrapped completely around the instrument, and brought under the thighs in such a manner that when the coverlid is turned aside, nothing whatever is visible except the open extremity of the instrument; a lighted candle is then held in the right hand in such a position as to throw a light upon the parts required to be seen, when, if the speculum has been applied in the proper direction, the os and cervix uteri will be brought into view. In cases where the vagina is very lax and dilatable, the extremity of the instrument sometimes passes by the cervix uteri into the *cul de sac* of the vagina; and here the cervix will only be partially seen, the os being altogether pressed on one side. It is better in these cases to withdraw the instrument slowly; and if, when it has been thus moved and drawn down to a certain extent, the parts are not distinctly seen, then I advise you to remove the speculum altogether, and to re-apply it, taking care to avoid the difficulty experienced in the first introduction. There is generally a good deal of mucus besmearing the parts, which must be wiped away before you can clearly discover their pathological condition.

Although it is upon the whole better for the patient to be in bed, it is by no means necessary. If a female should call upon you for advice, and you think her case requires the use of the speculum, the examination may be conducted with the same freedom from exposure if she recline on a couch without being undressed. In these cases the under-clothing should be wrapped round the patient in the same manner as recommended with regard to the sheet; and thus she will not be subjected to the annoyance arising from an exposure which is altogether unnecesaary, and extremely revolting to the feelings of a right-minded female.

It is scarcely, if ever, necessary to use the speculum in an unmarried woman. Its employment ought never to be sanctioned where the hymen is perfect, or where there is great narrowness or extreme sensitiveness of the vagina; where there are fungoid growths or extensive ulcerations of the uterus, which bleed freely on being touched. In the latter cases the flow of blood would effectually prevent you from seeing the condition of the parts on the one hand, whilst on the other the introduction of the instrument might be productive of injury.

Some men have violently opposed the use of a speculum under any circumstances; whilst others, by its frequent and unnecessary employment, have created no inconsiderable amount of disgust, and have thus materially damaged the reputation of the instrument. Avoid both these extremes: use it where necessary, but never employ it when the information required can be obtained by the touch. The cases which imperatively demand the employment of the speculum, are those in which there has been long-continued leucorrhœal or sanguineous discharge: the former are often considered by the female herself to be of no importance, and she seldom applies for relief unless it becomes profuse and she feels that her strength is giving way. The common term by which it is designated—"weakness"—shows the popular idea which is prevalent; namely, that it arises from a debilitated and relaxed condition of the parts locally, or of the system generally, or both these causes conjoined: and, without doubt, in many instances this opinion is correct. A patient applies to you evidently in enfeebled health, complaining of general debility and want of power: the surface of the body is pale and sallow; her pulse is feeble, her appetite bad; she has "a weakness upon her," and tells you she is unable to pursue her ordinary avocations, that "she has no heart for anything:' she is hysterical and dyspeptic; complains of no pain: there are, probably, some uneasy bearing-down sensations, and a dragging feeling in the lumbar and inguinal regions, especially if the flow occurs in a person who has borne children. You make a careful digital examination, and you find the local symptoms correspond with the general. There is profuse leucorrhœal discharge; the parts are much relaxed, the canal of the vagina somewhat shortened from the descent of the uterus, which has occurred in consequence of the loosening of its natural supports (the ligaments above, and the vagina below). The introduction of the finger gives no pain, and there is no resistance to its onward passage. If the vagina has been distended by frequent child-bearing, the membrane is often thrown into loose folds. The state of the uterus, and especially of its cervix, should be ascertained; and if it be found healthy, the speculum need not be used: you have by the finger acquired all the information you need; there is no organic disease—the local symptoms are clearly the result of general debility; and whilst you make use of means calculated to moderate the discharge, you will look more to the general system, as the cause from which all these symptoms are proceeding: for although the general debility must of necessity be increased by an inordinate local discharge, recollect that *this* is the symptom, and not the disease itself.

Leucorrhœa arising from this cause is very common amongst the poorer classes of the community, who are ill-fed, and reside in crowded and badly-ventilated apartments, and, as might be expected, exhibit all the signs of defective nutrition. In such cases, the indication is clearly to build up the powers of the constitution, which have been broken down. This is to be effected by the various forms of tonic medicines, conjoined with a liberal diet and a moderate portion of stimulating drink. It is better to commence the treatment by giving a mild aperient to clear away any feculent matter or morbid secretion that may be detained in the intestinal canal. The following draught is generally sufficient for the purpose:

℞ Pulv. rhei, gr. x.;
Potass. sulph., ℈j. ad ℥ss.;
Tinct. zinzib., ℥ss.;
Aq. menth. piper., ℥j. Ft. haust.

When the bowels have been relieved, you commence the tonic plan, beginning with the more mild forms, and gradually increasing their strength. Where there is tendency to nausea, the following infusion is of great service. It may be made the vehicle in which some more powerful medicine may be administered:

℞ Flor. anthemid.,
Cort. aurant. exsicc., āā ℥ij.;
Cort. limon. recent., ℥j.;
Aq. ferventis, Oss.

Macera per horæ sextam partem, et cola.

The maceration must be continued no longer than the time specified (ten minutes), or the

liquid will become intensely bitter, and far less grateful to the taste, and, consequently, not so so likely to be retained on an irritable stomach. To this infusion an alkali or a mineral acid may be added, according to the state of the stomach. If there be vomiting, four or five minims of dilute hydrocyanic acid, with a drachm of compound tincture of cardamoms, may be given thrice a day with advantage in an ounce of the above infusion. The nausea or vomiting having been relieved, a more decided tonic should be employed, such as calumba or gentian, combined with a full dose of taraxacum if there be a sluggish condition of the liver. A few grains of hydrargyrum cum cretâ may also be required; but great caution is necessary in the administration of this remedy. Its effect should be very carefully watched, as some constitutions are very intolerant of mercury, in any form and in the most minute quantities. The diet at this period should be light and nutritious, and in quantities proportioned to the digestive capabilities of the stomach. As soon as the dyspeptic symptoms have been relieved, one of the various preparations of iron should be substituted for the vegetable tonic. This mineral has long been in great repute in the treatment of vaginal discharges; and in the cases now under our consideration, where they arise from an enfeebled state of the general health, the remedy is extremely serviceable. The tinct. ferri sesquichlorid. in large doses is often very beneficial. This preparation acts not only as a general tonic, but also as a local astringent, checking to a certain degree the leucorrhœal flow: sickness is, however, produced in some instances by the tincture, and some other form of the mineral must be tried, *e. g.*, ferri citras, or ferri ammonio-citras, dissolved in mist. camphoræ. One of the most elegant (if the term may be allowed) of the ferrugineous preparations is the liquor ferri acetatis prepared by Warner and Barclay of Fore street. It contains a large proportion of iron, and scarcely ever produces nausea, even in a very irritable stomach. Ten minims constitute a medium dose, and this may be repeated three or four times daily in any convenient menstruum. It is better to apprise your patient of the blackening effect of iron upon the alvine evacuations, or she might otherwise be somewhat alarmed at their appearance. If the nights be sleepless, 10 minims of Davenport's chlorodyne may be administered with great advantage; it produces a very soothing effect, and is seldom followed by sickness or headache, which, as you are aware, are not uncommon after the exhibition of the usual narcotic medicines. A moderate quantity of port-wine, or stout, if it be preferred by the patient, should be allowed; and the diet should consist, for the most part, of animal food. If the patient reside in an unhealthy locality, removal from it into a more pure atmosphere will greatly expedite the cure.

Thus far the constitutional treatment, which, as I have said, is the more important. Nevertheless, the local must not be neglected, as profuse leucorrhœal discharges are in themselves very debilitating, and tend to increase the unhealthy condition of system to which they owe their origin. You, should therefore, employ local astringents at the very commencement; and it will be found necessary to vary them from time to time. You may begin with a solution of alum or sulphate of zinc, in the proportion of eight grains of the former or five grains of the latter to an ounce of distilled water: ablution with cold water every night and morning should also form part of the treatment. Should this not succeed, the alum or zinc may be dissolved in a strong decoction of oak-bark, or tannin may be tried. The nitrate of silver is another very useful injection, beginning with a moderate degree of strength (gr. iij ad ℥j.), and gradually increasing it. Whenever the nitrate of silver is employed, the female should be informed of its effects upon her linen: you know it is used in the preparation of "indelible ink," and, consequently, will permanently stain the fabric upon which it drops: some of our hospital sheets afford a standing proof of the truth of this statement. If the uterus remain prolapsed after the patient has been restored to health, she should be recommended to wear a nicely-fitting and well-constructed abdominal support.

THE PARASITICAL DISEASES OF THE HEAD AND FACE.

By GEORGE ROSS, M.D., &c.,

Author of the 'Constitutional Relations of Diseases of the Skin.'

No. IV.

(Continued from page 390.)

BALDNESS,—PORRIGO DECALVANS, ALOPECIA.

Baldness is a consequence of disease rather than a disease in itself; and its causes are numerous. They may be either constitutional or local, congenital or accidental, physical or moral. In some instances the hair follicles and secretory cells are irreparably destroyed; in others they are only impaired in their functions by previous disease. Baldness may attack both old and young, but men more frequently than women; and it may occur in patches, called *alopecia areata*, or extend over the entire scalp.

Baldness arising from *local diseases* may be a secondary result of any of the maladies already described, viz.:

1. *Of Ringworm.*—When the baldness is rarely complete; the rough surface of the skin usually exhibiting young sprouting hairs of a weak texture and woolly appearance. The roots of the hair not being destroyed, the hair may be recovered.

2. *Of Scall Head.*—As a consequence of this complaint, the baldness is generally complete; the patch being quite bare, smooth, thin, depressed, and shining. In this condition the disease is sometimes irremediable.

3. *Of Eczema and Impetigo.*—The scalp is grey and crusty-looking in these cases; but the follicles of the hair not being seriously injured, the growth of the hair may be renewed.

4. *Of Pityriasis.*—In this case, like the foregoing, the baldness is usually of a temporary duration.

5. *Vitiligo.*—Baldness is also a consequence of another disease, which is not, however, very common, viz., *vitiligo*, so called from its resemblance to calves' flesh. It occurs in roundish patches of various sizes, the skin being white and shining, or dead-white in colour. Spots of this kind are often congenital on the chest and hairy parts of the body. When this condition occurs as a disease, it "creeps along in one direction," as Bateman describes it, and chequers the surface; on the scalp and other hairy parts the hair loses its vitality, turns white, and falls off. It may be considered incurable.

There is another and a usual form of baldness, which does not appear secondary to any preceding local disease, which we shall call distinctively

Alopecia.—This may occur in spots, or prevail over the scalp generally. It is characterised by undue dryness and gradual withering of the hair, the roots of which are, at first, a little raised, and the surface of the scalp itself dry and scurfy. It is attended with slight itching, especially when the body is heated by exercise, free living, or the warmth of the bed; and there are sometimes small pustules present. The hair at length loses its hold of the skin, and falls out, leaving a darkish spot on the site of the follicle. When this loss of hair is extensive, the scalp looks shrunken, being deprived of a considerable portion of its subcutaneous fat. In this affection there is a wasting of the hair follicles; but these may be stimulated to renovated vigour by appropriate local and constitutional treatment.

CONGENITAL AND SENILE BALDNESS.

Congenital baldness is rare, and is allied to albinism. In these cases, the follicles of the hair, as Cazenave has pointed out, are not destroyed; their functions only are altered, there being always thin woolly-looking hairs on the surface. *Senile* baldness is common to us all, and, like the congenital affection, is incurable. It commences either at the temples or the vertex, and leaves a fringe of grey locks extending from ear to ear. Sometimes, however, it exceeds these limits. The causes of greyness and baldness, though frequently identical, are not always so. In greyness—*Canities*—the disease chiefly attacks the pigment cells, the growth of the hair continuing; in baldness these cells may not be injured, but the bulb may waste with atony or be destroyed by disease, so that the hair perishes. As the loss of hair over the temples confers a sager aspect than is commonly deserved, it is frequently coveted; consequently the circumstance of its incurability is not much regretted.

SYPHILITIC BALDNESS.

This is not an infrequent cause of premature baldness. When the syphilitic poison has thoroughly impregnated the constitution, it debilitates the vital powers, and impairs the nutritive functions of various tissues. The structures which it especially attacks are the bones, the mucous membranes, the pigmentary tissues, the absorbent glands, and the skin. In the latter organ we include the hair. Coincident with the loosening of the hair, there will exist generally certain scaly or other eruptions of a secondary nature, but these are not invariably present. No disease, moreover, is ordinarily perceptible at the roots of the hair; nevertheless considerable quantities fall as often as it is brushed.

BALDNESS AFTER FEVERS, ETC.

Acute maladies of various kinds, fevers generally, pulmonary consumption, liver disease, and all other affections that impair the vital energy of the system, cause atony of the hair follicles, and consequent baldness. In these cases, the alopecia lasts only so long as the system remains debilitated, and the hair returns as soon as the strength is restored. In some cases, as in fevers, the hair is lost, like the cuticle, by a process of exfoliation, having been separated by the morbid actions that have been going on in the follicles; in others, as in pulmonary complaints, the hair drops out from sheer debility of the structures.

THE INFLUENCE OF EMOTION.

Many curious instances are recorded of persons becoming grey from shocks of grief or remorse, or from the lengthened continuance of depressing emotions. A gentleman watching all night by the bedside of his dying wife, rested his head upon his hand. When the light broke in the morning, the hair on that side of his head which was in contact with his hand was observed to be quite grey. Numerous instances of a similar nature have been recorded. It does not appear that baldness has been often so caused.

THE INFLUENCE OF COSMETICS, ETC.

I have no doubt that the habitual use of certain substances, to render the hair stiff and fix the curls, exerts a most injurious effect

upon the roots of the hair. The diurnal use of soap, for example, in dressing the whiskers, is highly pernicious. The caustic soda contained in the soap dries the hair and parches the follicles, premature greyness being the result.

The parts that first turn grey are the whiskers and short hair immediately in front of and above the ear; differing in this respect from the course observed in baldness, which is first manifested either on the temples or the vertex. The hairs that grow last are the first to lose their colour; so also that portion of the hair of the head which appears last,—viz, that on the temples, which is late in appearing,—is the first to lose its vitality. It would seem, however, that the body-hairs obey a different law of growth and decay from those that cover the head. I do not think that the custom of wearing hats induces either baldness or greyness to any extent, as is frequently alleged. Each description of hair has its own period of life,—of development, maturity, and decay.

Pathology.—What has already been said suffices to explain the pathology of baldness. Gruby, however, says that it is caused by a parasite which is found within the hair. This parasite is identical with the parasite of ringworm and favus, already described.

(To be continued.)

FIVE CASES OF RUPTURED PERINÆUM CURED BY OPERATION, AND SUBSEQUENT DELIVERIES WITHOUT LACERATION.

By I. BAKER BROWN, Esq., F.R.C.S.

(Read before the Medical Society of London.)

Case I.—Ruptured Perinæum, complete—Operation—Cure—Subsequent Delivery without Rupture.

H. M., æt. thirty-eight, a lady from Essex, sent to Mr Brown by Dr Cape (who had not attended her in labour), mother of two children. The perinæum was torn in her first confinement, which extended over seventeen hours.

On Examination, Mr Brown found one-half of the sphincter gone, and some portion of the recto-vaginal septum; the anus was drawn upwards by the action of the levator ani.

June 18th, 1835.—Mr Brown operated, Dr Cape and Mr George Brown assisting.

21st.—Deep sutures removed.

28th.—Bowels moved.

July 11th.—Dr Cape saw the patient with Mr Brown, and on a careful examination the perinæum was found to be perfectly sound and entire, and the sphincter power restored.

This lady was, two years afterwards, attended in her confinement by Dr Cape, when the perinæum escaped quite uninjured.

Case II.—Rupture, complete—Previous Operation—Second Operation—Cure—Subsequent Deliveries without Rupture.

E. J., æt. twenty-eight, from Manchester, recommended to Mr Brown by Mr G. C. Jonson, of Grosvenor street, Eaton square, was admitted into St Mary's Hospital in July 1835. The perinæum was torn in her first confinement, on the 5th of May, 1835. Two months after the accident her usual surgeon in Manchester operated upon her, but only partially succeeded, as she did not recover control over the evacuations when they were loose, and she also suffered from partial prolapsus.

On Examination, Mr Brown found that the operation had succeeded in restoring the anus, but not the perinæum. The patient was weak and low, and complained of some difficulty in passing her water, especially if she retained it for long. This, Mr Brown found, arose from weakness of the anterior wall of the vagina, and consequent prolapse of the bladder into the vagina.

July 21st.—Mr Brown operated on her in the usual way. Union took place without one bad symptom, and in a fortnight she left the hospital to stay with a friend in the vicinity until her health should be quite re-established. Mr Brown subsequently heard from her in September, when she wrote that she was in the enjoyment of excellent health and strength. This patient has since been twice attended by his friend, Dr G. Stephens, of Manchester, and no injury has resulted to the perinæum on either occasion.

Case III.—Rupture, complete—Cure—Subsequent Deliveries without Rupture.

Mrs T., æt. thirty-five. The perinæum was torn during her confinement with her first child, eight years ago, the forceps having been employed; but the laceration was extended at the birth of her second child. The perinæum and sphincter were torn through, and the control over the sphincter ani lost.

Oct. 9th, 1856.—Mr Brown operated at Birkenhead, where this lady resided, and at this time she was advanced to the second month of pregnancy.

11th.—Dr Walker, her usual medical attendant, removed the deep sutures.

The bowels were moved on the 25th, and on the 20th of November she was reported as perfectly cured. She has since been twice delivered at the full period without any injury to the restored perinæum.

Case IV.—Rupture, complete—Cure—Subsequent Delivery without Rupture.

Mrs M. S., æt. twenty-five, from Surrey, came under Mr Brown's care, at Sir Chas. Locock's recommendation, in March 1837, who stated that her case was the worst he had seen. Four years before, she had been delivered, by the aid of forceps, of her first child, after a tedious labour. Two years after, she had a second child; but ever since the birth of the first, suffered from a rupture of the perinæum, which deprived her of the proper control over the action of the bowels, and, indirectly, seriously affected her health; she had been almost always obliged to maintain the horizontal posture.

Examination showed a complete rupture of the perinæum, about an inch of the recto-vaginal septum being also destroyed.

March 21st.—Mr Brown operated in his usual way, in the presence of and assisted by Dr Handfield Jones, and Messrs Britton, Staples, and Philip Harper; the late Dr Snow administering chloroform.

On the evening of 23rd, removed the deep sutures; and on the 26th, the superficial.

April 2nd.—When the bowels were suffered to act, a small recto-vaginal fissure was discovered, but this perfectly healed up in another week by the daily application of acetum lyttæ. From this time her recovery advanced rapidly; she regained her health, and was once again enabled to enjoy horse exercise, which she had not been since her first confinement.

Sir C. Locock examined the patient, and found the integrity of the perinæum restored in the most perfect manner.

In August, 1860, this lady was delivered at seven months and a half, by the advice of Sir C. Locock, by Dr Gream, who wrote to Mr Brown subsequently, stating that so perfect was the perinæum, and the absence of all traces of previous laceration, that he felt unable to credit the lady, that she had been so seriously injured as she stated: moreover, he added that the perinæum continued uninjured throughout the labour, although no special precaution was taken to prevent injury. Mr Brown had also since heard from the lady herself, that she is in all respects as well now as before her confinement.

Case V.—Ruptured Perinæum, extending two inches up the Rectum—Two Operations—Cure—Subsequent Delivery without Rupture.

Mrs R., æt. twenty-two, residing in Essex, forty miles from London, was delivered, after a tedious labour, by forceps, of a living child, on June 30th, 1858. Two days afterwards she had no control over the action of the bowels, produced by castor oil.

July 5th, 1858.—Mr Brown examined her, and found that the laceration of the perinæum was complete, and also of the rectum itself, for two inches. The rectal tear Mr Brown at once closed with silver sutures and a leaden plate, which was removed on the tenth day; and Mr Brown performed his usual operation for ruptured perinæum, being assisted by Messrs Parkinson, Taylor of Bocking, and Dr Bozeman of Montgomery, U.S. The deep sutures were removed on the third day; and in a fortnight she had control over the sphincter, and was quite convalescent. In six weeks from her delivery, she was down stairs.

Remarks.—This was only the second case in Mr Brown's experience where such a complete laceration had extended so far up the bowel; and yet it will be seen that such a rapid and complete restoration resulted from the operations, even whilst the lochial discharge was going on for the first two or three weeks. Dr Hodges, of Rochford, has since attended this lady at the full period, and no rupture of the restored perinæum took place. Dr Hodges lately related this case at the Obstetrical Society; but as the notes of the transactions of that Society, published in all the journals, do not mention Mr Brown as the operator, Mr Brown considered himself justified in publishing it himself, especially as Dr Hodges wrote to him, expressing his surprise and regret at the omission of Mr Brown's name.

THE SPIRIT OF THE PERIODICALS.

We extract from the 'Dublin Quarterly Journal' the following article, by Mr Clay, of Birmingham, on a

NEW SIGN OF POST-PARTUM DETACHMENT OF THE PLACENTA:

"The rules usually given in obstetric manuals and text-books for the management of the placenta, after the birth of the child, are—to wait for a pain, or to carry the finger along the cord to the os uteri, and, if its root can be felt, it may be fairly assumed that the placenta is thrown off, and may be easily extracted by gentle traction of the cord, with the aid of external manipulation. If these instructions be faithfully carried out, can we rely upon the facts elicited as infallible proofs that the placenta is separated from the uterus? Pain may mislead, as it frequently arises from other causes than contractions of the uterus; and even if the insertion of the cord can be felt, it is not always conclusive on this point, as the root of the cord may sometimes be felt when the uterus is in a flaccid condition, by using moderate traction on the cord, and yet the placenta be not thrown off. Besides, the patient often lustily complains of the smarting pains caused by the frequent examinations deemed necessary to ascertain the fact; and often she positively forbids such a mode of interference.

"Four years ago I was led, from these causes, to investigate the subject, with the view of improving, if possible, upon the old mode of managing the deliverance of the after-birth. I thus ascertained certain facts, from which I came to the conclusion that a very simple sign existed by which the separation of the placenta, after the birth of the child, might be indicated; and, having tested it in upwards of nine hundred cases, I hope I may be considered to be fairly entitled to lay the results at which I have arrived before the Profession.

"Before dividing the umbilical cord, I always apply two ligatures, and make both sufficiently tight to prevent the occurrence of hæmorrhage. If the maternal part of the cord is now examined, it will be found to be in a flaccid condition, and almost free from blood; but if it be again examined, at an interval, say from one to three minutes, it will be found to have acquired increased specific weight, and that the vessels are more or less filled with blood. The one fact may be ascertained by poising the cord on the fingers; the other, by slightly grasping the cord near the vagina, with the thumb and forefinger of the left hand, and, with the fingers of the right hand, suddenly compressing it, when a well-marked sense of fluctuation is perceived underneath the

fingers of the left hand,—a kind of resilience similar to the feeling produced when an elastic tube filled with fluid is suddenly compressed.

"When the placenta is thrown off, or sufficiently detached to give rise to a tolerably free hæmorrhage, the cord loses its increased specific weight and the hydrostatic property just mentioned. These phenomena occur so invariably, that the loss of the previously-acquired hydrostatic properties of the cord after the birth of the child constitutes the sign of detachment previously referred to.

"The whole of the phenomena are manifested in three stages, viz. :—1st, a state of flaccidity ; 2nd, a state of repletion ; 3rd, a state of flaccidity.

"If the umbilical cord be tightly grasped by a spasmodic contraction of the os uteri, or by irregular contractions of the body of this organ, the loss of the particular hydrostatic properties may be delayed for a brief interval ; but in a few seconds the spasm subsides, and those phenomena are produced which indicate the separation of the placenta, and that this structure may be safely extracted. These signs are, not, of course, always equally marked in every case,—often requiring experienced tactile management, in order to detect their presence. When the uterus is in a flaccid condition, the phenomena are manifested in a very slight degree, but are still perfectly reliable. On the other hand, when the uterus is contracted, with some degree of firmness, on the placenta, they are so well marked that the most inexperienced may readily detect them. In cases of partially-adherent placenta, the disappearance of the hydrostatic properties, after being once fully developed, and the failure to deliver the placenta by the usual manipulations, have always indicated to me the necessity for promptly adopting artificial detachment by the introduction of the hand. In twin cases, if the cord is firmly tied, I have invariably found that the signs persisted until the birth of the second child. In one case, where the hydrostatic properties disappeared, after being well marked, before the birth of the second child, I found, on examination, that the corresponding placenta was detached, and I at once removed it, which, otherwise would probably have been suffered to remain. Neither mother nor child incurred any risk.

"It sometimes occurs that the placenta is separated simultaneously with the birth of the child. In this instance, the first series of phenomena may be absent ; and it may be prudent to wait before proceeding to extract the placenta, although it may be generally effected with safety.

"The practical value of the application of these facts to obstetrics is obvious, as by merely compressing the cord in the manner previously indicated, the precise time of separation may be easily ascertained, the placenta at once extracted, and the patients thus freed from those frequent annoying examinations usually employed. The prompt delivery of the placenta, on the first efforts of the uterus, is very important, as this organ contracts then more efficiently, and the risk of hæmorrhage is not so great, and it may be fairly assumed that the puerperal convalescence is not so protracted as under a more dilatory proceeding.

"To students, or inexperienced practitioners, it might be a safe instruction to impart,—not to interfere in the extraction of the placenta so long as the hydrostatic properties herein defined are persistent."

The 'American Medical Monthly' opens with a continuation of Dr PEASLEE'S articles

ON DISPLACEMENTS OF THE UTERUS.

In this number the Author treats of *Inversion*. After some remarks to the effect that the inversion may be partial or complete, and that partial inversion may be of three kinds—viz., *depression*, implying convexity of the fundus towards the cavity of the uterus ; *introversion* or depression into the cavity of the uterus, and *perversion*, in which the fundus projects through the *os tincæ*, to which Mad. Boivin and Dugès add inversion of the body and cervix,—he says that inversion usually occurs immediately after the expulsion of the fœtus ; but it may also happen some days later, and it may be induced by a polypoid growth. The causes of inversion following labour are :

"A very prompt delivery (implying powerful contractions of the uterus), especially if it occur while the patient is standing or rising from stool ; rash pressure downward of the fundus uteri by the hand applied over the hypogastrium ; powerful straining efforts of the patient after the fœtus is expelled ; and all causes of irregular uterine contraction. But, doubtless, the most common cause is careless traction upon the cord, in order to remove the placenta after the fœtus is expelled. Still, it should be added that inversion may occur under the most judicious management. If the uterus be in a state of atony for a time after the fœtus is expelled, we may easily conceive that if an irregular contraction should take place, it might cause a depression of the fundus at first ; and this may finally become a complete inversion, independently of any error on the part of the practitioner."

The Author then continues :

"*Symptoms of Recent Inversion.*—If the inversion be *complete*, the following grave, rational signs present themselves. The patient suddenly becomes exhausted and deadly pale, even though there be no hæmorrhage. Generally, however, but not always, profuse flooding occurs, provided the placenta is detached. It is, however, far more frequently attached when the uterus is inverted. The pulse becomes small and rapid, and the voice weak, and nausea and vomiting usually supervene. If hæmorrhage attends, syncope soon follows, and in some cases death ensues almost immediately. On the other hand, if the patient rallies, she does so almost as slowly if there has not, as if there has been hæmorrhage ; the shock to the nervous system being the main source of immediate danger. Violent uterine contractions accompany, and also sometimes succeed, the displacement.

"Such symptoms should at once induce you to make a thorough local examination. A large tumour will be found hanging from the vulva, larger than the contracted womb should be ; at first flaccid, and sometimes extending half way to the knees ; but anon becoming rigid, from the supervention of contractions. This is the completely inverted uterus. If the vagina is also completely inverted (as it usually is not), there will be a firm constriction towards the top of the mass (the os uteri), and the portion above this is the inverted vagina. The cavity formed by the inverted uterus, and which is, of course, continuous with the peritoneal cavity, contains the ovaries and Fallopian tubes in all cases, and sometimes, also, portions of the small intestines, of the bladder, and the rectum. Thus, the size of the tumour will vary much, according as it does or does not contain the latter viscera. It is of course larger also, if the *placenta* is still attached.

"On inspecting the protruded mass, it presents a rough, fungous-looking, bleeding surface (if the placenta is detached), and we can distinguish the orifices of the uterine sinuses. The mass is spheroidal or ovoid, and larger above than below, and is sensitive to the touch ; and should, of course, be at once recognised if the placenta is still attached. On attempting to examine *per vaginam*, the latter may be found to be completely inverted. If not, the finger passes only a short distance into that canal, and can be carried completely around the upper end of the tumour without finding the os uteri. Examining *per rectum*, also, the uterus is not found in its place. And finally, search being made for it by palpation over the hypogastrium, it is thus found to be absent from the position it should occupy immediately after parturition.

"If the inversion be *partial*, the rational symptoms will be less pronounced proportionally to the degree of the displacement, and some of them will be entirely wanting. If mere depression exists, we may merely recognise a cup-shaped depression in the fundus on applying the hand to the hypogastrium. In introversion, this would be still more marked. In perversion, the fundus might not be reached at all by this manipulation, and there would be graver accompanying symptoms. But a vaginal examination would discover the fundus projecting more or less through the os, into the vagina, it being encircled as by a firm ring, by the os above. But even if the whole uterus except the os be inverted, the tumour may still be so small as to be retained in the vagina, since, unless there be complete inversion, nothing but the ovaries and Fallopian tubes, and not the whole of these, is contained in the cavity formed by the inverted organ ; and in this case, the tumour in the vagina has been mistaken for the breech of a second child.

"In regard to the comparative frequency of complete and partial inversion, I should add that most writers regard the former as comparatively quite rare. It is my own opinion, that of those cases occurring at once after the fœtus is expelled, the greater number are cases of complete inversion ; while those occurring subsequently are mostly cases of partial inversion.

"*Prognosis of Recent Inversion.*—Inversion is a fearful accident, unless treated at once, and the uterus reposited. But if judiciously and promptly treated, it is not usually fatal. There is, however, danger of a relapse for several days after, even to the 10th (Leblanc), and after a subsequent delivery. If overlooked or maltreated, it may prove suddenly fatal (in one or two hours), or death may occur a few days subsequently, from pain and exhaustion, syncope, or convulsions.

"On the other hand, if the patient survives an unreduced inversion for two or three weeks, she may probably for months or years, though still a great sufferer. Repeated and almost uninterrmitting hæmorrhage, however, generally limits the life of the patient two or three years after the accident (Boivin and Dugès, p. 123). Some, however, after a few months or years, experience but comparatively little inconvenience from this accident. At the end of from three to six months, the uterus will have been reduced to nearly its normal size, and will frequently no longer protrude from the vulva ; and if not, life is prolonged with much less discomfort. Levret and Delamotte were consulted by patients who had had inversion of the uterus twenty and thirty years, respectively. And Levret mentions the case of a woman seventy years of age, who had a complete inversion of the womb and vagina, and, of course, the mass was entirely external—which contained a portion of the rectum, of the bladder, and of the small intestine, besides the ovaries and Fallopian tubes.

"*Complications of Recent Inversion.*—Distension of the bladder and subsequent inflammation may be expected, if not guarded against, as complications. Sometimes, also, the uterus, if unreduced, becomes strangulated, and finally sloughs off ; and in a few instances, the patient has survived even this result. Inflammation soon supervenes of the displaced organ in all cases ; and this must, in cases where treatment has been delayed for a short time, be removed, before reposition is attempted.

"*Diagnosis of Recent Inversion.*—It might be supposed that the diagnosis of recent inversion, when complete, presents no difficulty ; but it has, in practice, often been found otherwise. The sooner after the accident occurs, however, the easier the diagnosis.

"1. From a *polypus*, complete recent inversion is distinguished by its rough, bleeding, and sensitive surface, and its form (larger above than below), and the greater immobility of the tumour. In polypus also the os encircles the tumour ; not so in inversion when complete.

"2. From *prolapsus*, inversion is distinguished by the absence of the mouth of the uterus at the lower part of the tumour, as well as by the blood-red and bleeding surface presented.

"3. From *prolapsus of the vagina*, by its rough bloody surface, and firmness, and difficulty of reduction.

"The history of the case in either prolapsus or polypus will also, of course, be inconsistent with the idea of recent inversion. Moreover, the absence of the uterus from its normal position in the hypogastrium, and the placenta also, if attached, will distinguish inversion from all the preceding ; and in polypus and prolapse of the vagina, the finger may be passed above the tumour into the vagina.

"*Partial* recent inversion (in the third degree, or perversion), may be mistaken for (1) polypus. But here, again, the tumour is sensitive, while polypus is not ; the surface is rough and bleeding —that of polypus is polished and smooth. Sometimes, however, the inverted uterus, whatever the degree of inversion, is not decidedly sensitive. (2.) It may also be mistaken for *prolapsus ;* but here, again, the surface of the latter is smooth, and the os uteri at the lower extremity of the tumour.

"The diagnosis of the first degree of recent inversion (depression and introversion) is made out especially by searching for the fundus uteri by palpitation of the abdomen above the pubes.

"*Treatment of Recent Inversion.*—Evidently the first thing to be done in a case of recent inversion, whether complete or partial, is to return the uterns to its normal position as promptly as possible. A delay of a few minutes may be fatal to the patient, and the difficulty of reposition is also much enhanced as the time passes. Denman thought the lapse of four or five hours might render the reposition impossible. This is, however, a mistake, as will appear further on.

"If present, therefore, when the displacement occurs, we should not lose a minute before attempting to restore the uterus to its normal position. There is, however, an important practical question to be settled in each case, provided the placenta is still adherent (and it is so in a majority of cases), viz.: Shall the placenta be detached before the attempt is made to reposit the womb?

"Blundell, Burns, Clark, Carus, Denman, Gooch, Newnham, and others are opposed to the removal of the placenta before attempting the reduction; though Denman and Carus advise to complete the detachment, if it be already partially detached. On the other hand, Baudelocque, Boivin, Capuron, Gardien, Radford, Meigs, and others, advise previously to detach the placenta. Obviously the reduction will be greatly facilitated by its previous removal, and in this way we also avoid any trouble from it subsequently to the reposition; but those who would return it with the uterus are deterred from detaching it by the risk of hæmorrhage. Dr Radford has, however, shown that this risk has been overestimated. Avoiding all discussion, I should say, that our practice, in case the placenta is still adherent, may be safely based on the three following precepts:

"1. If the placenta is partially detached, complete the detachment before attempting the reposition.

"2. If the placenta is adherent, and you are present at the moment when the inversion occurs, attempt to replace the uterus at once, without detaching the placenta. You would generally succeed at once, and the placenta will be expelled by the uterine contractions afterwards.

"3. If not called till an hour or more has elapsed, or until the uterus has become rigid, detach the placenta before attempting to replace the womb.

"To effect the reposition, the patient should be placed on the back, with the pelvis higher than the shoulders; and if the uterus has become rigid, it will be necessary to administer an anæsthetic. In case of a few hours' delay, the bladder and rectum should also be previously evacuated. In respect to the manipulations to be resorted to, different directions are given by different writers. But first apply oil or glycerine to the hands. Mr Newnham advises to attempt to replace first the portion of the mass which last descended, and therefore to commence at the upper part of the tumour. Some advise to compress the whole mass between the two hands, to diminish its size, and then to force the mass upwards, and thus effect reposition. I should compress the tumour in this way only in case it contained portions of intestine, and for the purpose of forcing them back into the peritoneal cavity before reposition is attempted.

"I should endorse the practice of those who first apply the end of a single finger to the lower extremity of the tumour with the intention of indenting it like the bottom of a bottle, by forcing it upward, and then other fingers, and finally the whole hand, when the indentation becomes sufficient to receive the latter. It will generally require a firm, continuous pressure, for several minutes before the lower part of the tumour yields at all; and when at length it does so, and the whole hand is applied in its turn, we must expect to meet with resistance again, when the inverted fundus is raised to the level of, and before it is returned through the os. A steady pressure will, however, at last overcome this, and the uterus is then at once replaced; the fundus sometimes starting from the hand, at last, like an elastic bottle when turned wrong side out. The hand must, however, (now within the uterus,) be carried as high as possible, to make it certain that no depression of the fundus remains. It should also be retained in the cavity of the uterus until expelled by the contractions of the latter; since, otherwise, the contractions may reproduce the inversion.

"We must, however, know when to attempt this manipulation. And Dr Meigs has decided this point. He observed that after-pains (*i.e.*, contractions) occur in the inverted uterus, as after parturition under normal circumstances. During them, of course, the uterus becomes rigid and firm, but the contraction ceasing, it again becomes flaccid. It is only when in the flaccid condition, of course, that we are to attempt the manipulation just described. If we find the uterus rigid, therefore, we have only to wait until relaxation ensues.

"Since, however, continued pressure with the finger becomes at length quite fatiguing and painful, we may use with the same result a piece of cork an inch in diameter (a cork stopper, for instance), made convex at its extremity and attached to a piece of whalebone or wood of sufficient firmness, instead of the finger; and when the tumour becomes indented below by the pressure thus applied, the hand can be used in turn.

"If reduction is found to be impossible by the preceding process, and the principal resistance is afforded by the os uteri, it may be proper to divide the latter. Belladonna ointment may be previously applied, as recommended by Chaussier. If the uterus is inflamed when we first see the case, the inflammation should be diminished by bleeding, the application of leeches, &c., as may be required, before attempting the reduction.

"If all the preceding means fail, I should still be disposed to vary and repeat the procedure, since I think that but very few cases of recent inversion should be abandoned as irreducible. A few cases of partial, recent inversion have been spontaneously reduced; but we have no right to expect this termination in any given case.

"After the reduction has been effected, a recurrence of the accident is best prevented by keeping the patient longer than usual, after confinement, in a recumbent position. I have said nothing of brandy and ammonia, or other stimulants which the patient may require, according to her condition, before commencing or during the reduction."

The Author then considers the subject of inversion of long standing, to which we will revert in our next Number.

Dr Pavy's Lectures on *Diabetes* are continued in the present number of the 'Lancet.' We will reproduce an extract in our next Number.

Dr William Pirrie continues in the same journal his observations on *Favus*, from which we will make an extract next week.

The following Case of

TYPHLO-ENTERITIS

is reported by Dr W. P. Harris, of the Punjab Infantry, in the same journal.

"Usgar, a Malay, aged forty-five, employed as a lamp-trimmer on board the 'Viscount Canning' transport steam-ship; has flabby muscles, and the expression of a man who continually indulges in some intoxicating substance. He states that for the last two months he has occasionally suffered from constipation, though in other respects he has enjoyed his usual state of health.

"On the 5th of June he applied to me, stating that he had almost constant vomiting, much pain over the epigastrium, and was constipated; pulse quiet; tongue clean. Calomel and opium, followed by castor-oil, afforded much relief. He returned to his work, and on the following day stated that he felt quite well, with the exception of a little pain over the epigastrium, which was immediately relieved by the application of a mustard poultice. His bowels acted the same day.

"On the 7th he came back to me in a much worse state than he was on the 5th, though the symptoms had undergone much modification. He was suffering from severe pain and tenderness over the abdomen, aggravated towards the cæcal region, in which part there was a distinct fulness and hardness of the abdominal walls perceptible. He had no vomiting, and instead of his bowels being constipated, he was now afflicted with somewhat profuse diarrhœa, of a slightly slimy character. The expression of his countenance denoted much suffering; though, as usual amongst Orientals, the ordinary condition of health of his tongue, skin, and pulse, was not materially altered. Not, being possessed of leeches, which were clearly indicated, I gave him mercury with chalk and Dover's powder, in repeated doses, with fomentations and poultices to the cæcal region.

"June 8th.—A defined hard tumour to be felt this morning in the cæcal region, of about the size of a large orange, exceedingly tender to the touch, more so than yesterday. A couple of cupping-glasses were applied over the tumour, and the powders and fomentations continued.

"7th. The pain was much less this morning; the gums slightly affected, and the man expressed himself as feeling considerably relieved. The powders were reliuquished; fomentations to be continued as before.

"After this date there was a daily improvement up to the 28th, on which day I disembarked with my regiment. During this period the diarrhœa continued, though less profusely than at first, being kept in check by means of dilute sulphuric acid and tincture of opium. No strong astringents were given to check this flux, as nature appeared to use it as a means of diminishing the size of the tumour, which slowly reduced in bulk without the patient being weakened by the relaxed state of the bowels. To assist nature, compound iodine ointment and mercurial plasters were applied, and hydriodate of potass with decoction of bark given internally.

"On the 28th, when I gave up the treatment of the case, the man had returned to light employment, and the tumour was inconsiderable in size.

"I lost sight of the man for about one month, at the expiration of which time I found that nature had perfected what I had left incomplete; as, on examination, I could find no trace of a tumour, or even of any hardening of the textures, and the man had gained more flesh than any of his friends had seen him possessed of before. The patient told me that the diarrhœa had continued until the whole of the swelling had disappeared. The improved state of health over that he had enjoyed for some years past may, perhaps, be referred to the fact of his having lately been unable to obtain opium, which, for the last two years, he had been in the habit of eating."

The 'Medical Times and Gazette' contains the tenth Lecture of Dr Goodfellow

ON DISEASES OF THE KIDNEY.

He treats of the process of formation of the *small hard, contracted kidney*. He thinks it a combination of the processes of degeneration and inflammation. He observes:

"In this form of kidney there is a great increase of the connective tissue, and not only an increase, but an alteration of the tissue. It is coarser, and is sometimes, I believe, more or less mixed with fibres of the yellow fibrous element. The normal connective tissue, or matrix of the kidney, is extremely delicate; and this, I suppose, has led some Histologists to deny its existence altogether. It is very easily destroyed, and it is so extremely transparent that unless considerable care is taken in the management of the light in looking at specimens of healthy kidney tissue as transparent objects, and, therefore by transmitted light, all appearance of fibres will be lost.

"The atrophy and destruction, partial or complete, of the Malpighian bodies, and convoluted tubes, which produce the contracted state of the organ, is, in a great measure, owing to this increase and alteration of the fibrous elements. Not altogether, however; for it is probable that, for the reasons assigned in my last Lecture, there is, at the same time, and from the same cause, a degeneration and actual wasting of these structures, independently of the mechanical effects of this increase of fibrous tissue. It is more than probable, as I there hinted, that the delicate anatomical elements composing the walls of the capillary blood-vessels, both Malpighian and secondary, and of the uriniferous tubes, are directly injured by the irritating influence of the alcohol, and other allied substances."

The increase of the fibrous tissue having taken place, how is it likely to affect the true secreting structures?

"It produces it in two ways, both mechanical in their operation,—First, by pressure upon them, leading to absorption, and secondly, by pressure

upon and obliteration, partial or complete, of the blood-vessels, and in this way cutting off the supply of nutritive blood-plasma. This interception of blood-plasma may probably be induced in another way,—by the peculiar mode of action of the causes of this form of kidney disease, either from actual coagulation of the albumen and fibrine in the blood-vessels, or from the mechanical influence of the separated or precipitated fats in a non-saponifiable form.

"But, as I said before, I do not think that the atrophy and destruction of the true gland structures are entirely due to these mechanical influences, certainly not, when the cause is alcohol. I repeat that the mere contact for any great length of time of an irritant with the delicate gland-tissues will lead, under certain conditions, to their degeneration and ultimate destruction, somewhat in the manner described in my last lecture. The mere contact, more or less continuous, of an irritant, such as alcohol, in the form of brandy, gin, and such ardent spirits, will produce something resembling a shock upon the tissues, alter or annihilate their inherent properties, impair or destroy the play of their normal chemical affinities, and consequently deprive them of their assimilating powers. They die, and cease to be renewed, from inanition, much in the same way as they lose the same properties of development, growth, and conservation, from general impairment of all the functions of the body in old age."

Dr Goodfellow then considers the mode in which the mixed varieties are produced; but having given that of the typical forms, we shall not follow him in this part of his disquisition. He then speaks of the fatty and amyloid forms. On the *fatty* form he remarks:

"We should, consequently, expect to find this superabundance of fatty matters in the body, and the tendency to the replacement of protein principles by fat in elderly people, in whom the respiratory changes are deficient, who take but little exercise, and take more food than they can possibly convert and assimilate into the higher proximate principles and protein-tissues. In drunkards this conversion probably is more nearly allied to a form of inflammation, and owes a complex causation. As I have already stated, alcoholic drinks are a much more frequent cause of this fatty kidney. It is impossible that the separation of fatty principles, which was observed by MM. Lallemand, Perrin, and Duroy, after the administration of alcoholic compounds, can take place in the blood without obstructing the circulation through the minute capillary blood-vessels, interfering with the transudation of blood-plasma through the interstices of their walls, and leading to a superabundant admixture of those fatty principles with the plasma itself, even if it were otherwise normal in composition, which it very probably is not. How can it, indeed, remain in the normal state? This separated fat most probably comes chiefly, if not entirely, from the red blood-corpuscles, if it be true, as Lehmann asserts, that the fats of the blood are principally deposited in them. It is not surprising, then, that tissues, whether composed of fibres, molecules, or cells, or of all of them, should undergo changes which ultimately end in fat. Old age, too much food, too little exercise, residence in an impure atmosphere, but above all, an intemperate use of ardent spirits,—one, or more, or all, are the true causes of the fatty form of kidney when occurring as an independent form of Bright's disease, and also, in great part, when it is an engraftment upon the others."

Again of the *amyloid*:

"Virchow was the first to discover the true nature of the metamorphosis that the tissues undergo in this condition of the organ. Those parts of the kidney, and of other organs which have undergone this metamorphosis, seem to be converted into a substance analogous in its reactions with iodine and sulphuric acid to substances of the amylaceous group. On brushing over parts affected with this metamorphosis, they assume in a few minutes a deep red-brown colour. This seems to be distinctive, for it is very different from the colour produced by iodine on organs in any other condition, and when once seen, is represented by Dr Harris not to be mistaken. It is not cellulose, for iodine does not produce the red-brown colour with this substance, and it offers less resistance to alkalies, and is convertible into sugar, which the amyloid substance is not. For the same reason it is not actual starch. The reactions with cholesterine with the same agents, for which it might otherwise have been mistaken, are essentially different. It is therefore not allied, probably, in any way to this substance. The process by which the presence of this amyloid substance may be detected is very simple, and of easy application. 'When a solution of iodine is brushed over a liver which has undergone this change, the affected parts in a few minutes assume a deep red-brown colour, very different, as before stated, from the colour produced by iodine on organs in any other condition. When to these parts, thus reddened by iodine, sulphuric acid is added, a change to a bluish-red or violet-red, or deep-blue purple, or even to an indigo-black, speedily commences; in some cases this colour quickly passes into a deep reddish-brown. In the Malpighian bodies, and arteries of the kidney, the bluish coloration is most marked, and in these the dilute acid is sufficient to produce it. In the liver the stronger acid is necessary, and the colour is observed with greater difficulty. Now, cholesterine, when treated with strong sulphuric acid and iodine, shows a very similar blue colour; but with iodine alone it is unchanged in colour. It is necessary, in order that the iodine shall produce its characteristic blue colour, that it undergo some amount of oxidation by the sulphuric acid.' The following are Virchow's views as to the nature of the substance, its anatomical seat, and the character of the constitutional symptoms, as quoted by Dr Harris, from his work on 'Cellular Pathology:'—

"'Almost all parts of the body are capable of undergoing this process of degeneration. The affected parts become enlarged, somewhat indurated and anæmic; the cut surface is semi-transparent, but dull; the natural colour of the parts is lost, but the colour of the neighbouring parts and vessels being seen through, gives them a yellowish or brownish tinge. The coats of the small arteries are the most frequent primary seat of this infiltration, and from them it spreads to the parenchyma of the organs; the walls of the arteries become thickened, and their calibre reduced, and hence the anæmic condition of the organs. The muscular fibres of the middle coat are the parts first affected. In the place of each muscular cell a compact homogeneous body is seen, in which, in the earlier stages, the centre of the nucleus appears as a hole; this afterwards disappears, so that a kind of spindle-shaped body remains, from which all trace of cell-structure has vanished, no distinction being left between cell-wall, contents, and nucleus. When the infiltration has reached this point, it commences to invade the parenchyma of the organs. In the liver, the cells in the immediate neighbourhood of the hepatic arteries are first affected; the liver-cells gradually become homogeneous; nucleus and cell-wall gradually disappear; and at last nothing is left but an absolutely homogeneous shining body; the cells are thus coverted into a kind of corpora amylacea. In the kidney, the vessels of the Malpighian bodies and the afferent arteries first undergo this change. In the earlier stages but little alteration is perceptible to the naked eye; the kidney appears merely indurated and anæmic, and only when a solution of iodine has been applied to it, does the change it has undergone become apparent; then, throughout the cortex numerous fine red dots appear, corresponding in their size and position to the glomeruli, and fine red streaks running from them indicate the afferent arteries.'

"'The disease is constitutional; one organ alone is rarely affected; the only spot where as yet an independent development of this change has been remarked, was in the permanent cartilages. The organs thus affected cease to discharge their functions; the patients assume a cachectic appearance, and gradually waste away; dropsy frequently supervenes. Sometimes, too, the whole digestive tract is affected by this degeneration. During life this is rendered manifest by continued diarrhœa, and by diminished powers of absorption.'"

Dr Goodfellow then discusses the formation of cysts, which he regards as an almost inevitable condition of Bright's Disease. They are of two kinds; one about the size of a walnut, and the other of a microscopic character. He observes:

"They are represented (and I believe truly) to be formed in three ways: First, and most frequently, in the way described by Dr George Johnson, which is so palpable as to occur to the mind of every one who is in the habit of examining attentively the kidney when so affected; and secondly, that suggested by Mr Simon; and thirdly, by spaces formed in the fibrous structure, which become filled with fluid. There is no doubt that cysts are formed in other parts of the body, according to this third mode of development; but whether they are in like manner formed in the kidney is very far from being proved, although it is certainly probable. There are much stronger grounds for our assent to the two first modes of formation."

The Author then briefly explains these processes of formation.

In the same journal, we observe a continuation of Mr Le Gros Clark's Lectures.

STRICTURE.

The Author reports two cases, and makes some remarks. Speaking of the formation of abscess, extravasation, and gangrene, he says:

"More usually, however, when time is given, Nature makes provision to obviate this wholesale destruction from diffused extravasation; and this is apparently accomplished, as in the cases I have narrated, in the following way: A diseased condition of the urethral mucous lining, consequent on gonorrhœa, and entailing stricture, is usually the antecedent state and history. A small point of ulceration in the urethra, possibly at one of the numerous lacunæ, extends outwards into the submucous areolar tissue, and is followed by a minute drop of urine. Inflammatory deposit takes place around this small fistulous opening, which is thus, as it were, walled in, as an ordinary abscess frequently is. But still the irritation of the urine, combined with the *vis a tergo*, gradually forces a passage onwards, and the centre of this indurated deposit at length softens down into a circumscribed abscess, to which the urine has access. At this stage the patient may come under our care, suffering from a hard swelling in the perinæum, often conical in form, with its apex directed forwards, and acutely tender; perhaps attended by complete retention of urine, or at any rate by difficult micturition. There is no fluctuation in this swelling; but on cutting through hard gristly texture, generally of considerable thickness, an abscess, containing, it may be, only a few drops of matter, is reached, and relief is afforded. If the case runs on to a later stage, as in the two instances mentioned, the pus and urine mixed finds a way out for itself; and this may be without extension of the infiltration, as in the first case, or with it, as in the latter. Still, the treatment must be the same—viz., free incision into the seat of abscess. But by this step we reach the urethra, and thus have it in our power to relieve the cause of the existing mischief, as well as the mischief itself. Now, it is to this point that I wish particularly to direct your attention; for I think this *desideratum* is best fulfilled by the non-interference plan which I adopted in the cases I have narrated—abstinence, I mean, from further interference after the abscess was freely incised, and the urethra laid open behind the point to which the staff was passed down. I have tested this plan for a long time now, and have no hesitation in recommending it for your adoption as a general rule, in preference to passing a catheter on into the bladder, even if you can accomplish this often difficult task, and leaving it there. Theoretically, the latter course seems to be the most appropriate, and I believe many Surgeons regard the introduction of a catheter as an essential part of the treatment. I used to think so, but am now satisfied, and have long been so, that, as a general rule, the presence of an instrument under these circumstances is not only superfluous, but positively mischievous. There may, doubtless, be accidental conditions which demand it, such as stricture farther back, which is, however, very rare, or a paralytic and distended state of the bladder; but even with dribbling incontinence this is not essential, as Case 1 proves. If the urine do not flow readily at once, it very soon finds its way

through the artificial opening; and we may then trust safely to Nature's modelling power, as we do, for instance, in lithotomy, without supplying a mould for the new material to be modelled upon. This reparative power was well illustrated in the case of extensive sloughing after extravasation to which I have referred. But, beyond this negative recommendation, you save the patient much inconvenience, if not suffering; and I have repeatedly seen the presence of a catheter create so much irritation, that healthy action has been retarded, and even arrested, and its removal thereby imperatively demanded. As the case advances towards a cure, then an instrument, either bougie or catheter—I prefer the former—may be introduced from time to time, to assist in enlarging the calibre of the urethra, but it need not be left in.

"You will not, however, understand me as advocating the treatment of burst urethra from violence in this way. In such cases it should be the Surgeon's first duty to introduce an instrument, and to fix it in the bladder. This can generally be accomplished by careful and patient manipulation, and of course without an external incision, unless the mischief resulting from infiltration require it. Indeed, it is the Surgeon's business to anticipate such mischief, and to pass a catheter, where he suspects the urethra is ruptured, before he allows the patient to attempt to micturate unaided. A case in point occurred under my care a few months since, and I commented upon it in a former lecture. A similar case came under the notice of several of you at an earlier period, in which a railway-guard was struck by the buffer of an engine, and had the ramus of his ischium fractured, and his urethra torn; both of these patients recovered without extravasation, from careful attention to this precaution; and thus, by allowing the urine to drain off through the instrument, so as to prevent the bladder from becoming distended, a ruptured urethra is not necessarily followed by extravasation."

Mr GREENWAY, of Plymouth, contributes a paper to the same journal on a

NEW OPERATION FOR IRIDECTOMY.

He says:

"Notwithstanding the various contrivances which have been devised for operating on the iris, I am not aware that any method has been adopted whereby a circular incision can, with certainty, be produced. In whatever part of the body Surgical aid may be required, it is, doubtless, the duty of the Surgeon, to the best of his ability, to leave the part affected in a condition to fulfil, as nearly as possible, the purpose for which Nature intended it. With this belief, I have been led to devise an instrument, the nature of which I believe to be entirely new, for producing an artificial pupil in the natural position and of a circular form.

"The instrument somewhat resembles a syringe, but, instead of being furnished with an ordinary nozzle, a canula is screwed on to the end of the cylinder, or body, and, there being no piston, the rod, which would otherwise be the piston-rod, is continuous with a blade which lies within the canula. This rod passes through an air-tight fitting at the upper part of the cylinder, and has a spring action. The canula is plano-convex transversely, its bore being one-twelfth of an inch by one-fifth; the plane surface presents near the extremity a circular aperture, about one-eighth of an inch in diameter, for the admission of a portion of the iris; that small portion of the tube beyond this aperture is filled with lead, which serves not only as a plug to completely obstruct the extremity, but as a point of resistance for the blade. On the convex surface is a small mark which indicates the position of the aperture on the plane surface.

"The blade is kept in close contact with the floor or plane surface of the canula by means of a spring which is interposed between it and the roof or concavity of the canula. Communicating with the upper part of the cylinder is a metal tube, about an inch in length, on which is fixed an india-rubber tube, which is furnished with a mouth-piece at its free end. This may be termed the suction-tube. On the opposite side of the cylinder is fixed a ring to receive the finger of the operator.

"It will be evident that if a person placed the mouth-piece between his lips, and caused suction, a current of air would pass in at the circular aperture of the canula, and that if this aperture were placed in apposition with a thin structure, such as the iris, a small portion of it would be drawn into the canula in the form of a cup. If, now, the blade be pushed forwards by pressing the head of the rod, the enclosed structure, answering to the shape of the aperture, would be excised, immediately the edge of the blade came in contact with the piece of lead which fills the extremity of the canula beyond the verge of the aperture.

"The experiments I have made on the eyes of animals, supplied from the slaughter-house, have been most successful. I found that I could, without fail, excise a perfect disc from the iris in its natural state, thereby leaving a corresponding aperture. In some cases, I produced an aperture so near the pupiliary margin as to leave only one-twentieth of an inch of iris, and that in an uninjured state, between the natural pupil and the artificial one. I may, therefore, fairly presume that in cases of closed pupil, for which the instrument is intended, the results will be equally satisfactory."

Mr ZACHARIAH LAURENCE continues in the same journal his papers on the *Utrecht School of Ophthalmic Surgery.*

We continue this week our quotation from Dr SIMPSON'S Lectures on the Diseases of Women, which appeared in the 'Medical Times and Gazette' of the 8th inst. On the subject of

PUERPERAL HYPOCHONDRIASIS,

Dr Simpson remarks:

"Before closing these observations, allow me to direct your attention for a minute or two to a morbidly-depressed state of mind which you will sometimes meet with in practice, weeks or months after the patient has been confined. When a patient has been much pulled down by hæmorrhage, or becomes exhausted by nursing, a state of anæmia or chlorosis, attended by more or less mental depression, want of energy, and loss of memory, particularly of proper names, will supervene, requiring the administration of an improved diet, wine, and tonics, such as iron and quinine. But occasionally an analogous degree of mental misery and depression comes on without any preceding hæmorrhage, and when the mother has not acted as a nurse at all. These cases are generally cured by the tonic means I have just alluded to; by change of air and scene, when that is practicable; and in some obstinate instances, where these measures fail, you will find Dr Seymour's plan of steadily giving an adequate opiate every night, to be a mode of treatment followed by the best results. Of this type of disease I lately saw a very marked case that had utterly defied all the proposed modes of treatment, and that yielded at last with a rapidity which astonished both the patient and myself, under the use of the tincture of the black snakeroot, or actea. This plant, the *Actea*, or *Cimicifuga racemosa*, has been long spoken of as a remedy for rheumatism, and particularly in the more acute forms of the disease. In the edition of Gray's Supplement to the Pharmacopœias, published in 1821, you will find the use of it in rheumatism stated. Latterly it has been employed by some American Physicians as their most valuable remedy in acute rheumatic fever. My very intelligent and excellent friend Dr Voris, of Rochelle, New York, told me, two years ago, that since employing the tincture of actea in rheumatic fever—and it is a very common disease in his district—he had seen the disease almost always cut short before the eighth or tenth day; the drug acting apparently as a simple antidote to the rheumatic poison, and curing without diuresis, diaphoresis, or any other discharge. The American Physicians give a strong tincture of the root in acute rheumatism in doses of thirty to sixty drops every two, three, or four hours. It may be given, if you choose, along with alkaline salts, or other anti-rheumatic drugs. I have found it, in my own case, repeatedly cure an attack of lumbago with wonderful rapidity. Some of the American Practitioners who have written upon actea, have spoken of its use in terms that are, no doubt, exaggerated. Thus, Dr Davis, of Chicago, says that, after much experience, he has no more doubt of the efficacy of actea in the early stage of acute rheumatism, than he has of the power of vaccination as a preventive of small-pox. But our American brethren have used actea also in chorea and other anomalous forms of nervous disease. However unlike rheumatism and chorea may look to the superficial observer, yet the able investigations of Dr Begbie and other pathologists have shown, as you are aware, an analogy, if not an identity, between the blood-poison which produces rheumatism and that which produces chorea. Dr Physick, of New York, and Dr Jesse Young, of Pennsylvania, about thirty or more years ago, recommended actea strongly in chorea. Latterly, Drs Lindsey, Kirkbride, Otto, and others have published their experience in favour of the same drug in this disease. In a case of anomalous and severe chorea of long standing, which was under my care some months ago, the actea was given with excellent effect. The patient had been previously treated, both in France and in this country, with zinc, iron, arsenic, and all the usual remedies employed in this malady.—But I have made all this long episode regarding the actea, not so much to speak of its use in the preceding diseases, as of its use in puerperal hypochondriasis and depression. A lady, the mother of several children, was twice the subject of the most painful mental despondency a month or two after delivery. On one of these occasions she was confined in London, and had the advice of several eminent physicians; but the disease took a very long and tiresome course, seemed to defy entirely all remedies, and gradually and very slowly terminated. On the last occasion on which the attack occurred, this patient was confined under my care here, and went home to England some weeks subsequently, perfectly well. She returned, however, in about a month to Edinburgh in the lowest possible state of depression, a perfect picture of mental misery and unhappiness. I tried many plans to raise her out of this dark and gloomy state. All failed. At last, fancying from some of her symptoms and complaints that there might be a rheumatic element in the affection, I ordered her fifty drops of tincture of actea thrice a day. After taking one dose she refused to continue it, as the drug had a taste so similar to laudanum, and as all opiates had always made her worse. On being reassured that there was no opiate in the medicine, she recommenced it, without any faith, however, in the results, as she had in a great measure lost faith in all remedial means. When I saw her next, some eight or ten days afterwards, she was altered and changed in a marvellous degree, but all for the better. On the third or fourth day, as she informed me, the cloud of misery which had been darkening her existence suddenly began to dissolve and dispel; and in a day or two more she felt perfectly herself again in gaiety, spirit, and energy. But nothing would induce her to give up the actea for six or eight weeks longer; and the last time she passed through Edinburgh, she told me that she had prescribed her own remedy to more than one melancholic subject with nearly as great success as she had used it in her own case. Will it be of use in many such instances? I know not. But *nous verrons.*"

A NEW OPERATION FOR AMPUTATION OF THE FOOT.

Dr George Mann, Newfane, N. Y., says: "I noticed in your September No. an article from Dr A. P. Smith, taken from the 'Maryland and Virginia Medical Journal,' recommending a new operation on the foot, viz. that of cutting though the metatarsal bones, instead of disarticulating, as usually recommended.

"It particularly attracted my attention, having assisted Dr A. M. Helmer, of Lockport, N. Y., to perform this operation in July last, with perfect success. Up to that period, we had never seen or heard of the operation. Dr Helmer had occasion to make an amputation above the digital extremities of the metatarsal bones; it was determined to save as much of the arch of the foot as possible, consequently he sawed though the bones about one-quarter their length above the digital extremities, cutting the first and fifth a little shorter than the rest, thereby leaving a slightly convex surface. This plan enabled him to cover the stump with a generous flap, which healed kindly, and the patient, a man aged about forty years, an inmate of the Niagara County Poor-house, is now able to walk nearly or quite as well as in many instances where the entire bone is left.

"Why has so simple, and, in my estimation, so judicious an operation, not been recommended before?"—'American Medical Monthly.'

AN ADDRESS

TO THE

MEMBER OF THE MEDICAL PROFESSION.

The Eighteenth Volume of this Journal commences January 2, 1861.

In accordance with our custom, we address a few sentences to our Professional brethren at the conclusion of the year, on our past labours and future prospects. Our first words must be expressions of gratitude for the generous and rapidly-extending support which the MEDICAL CIRCULAR has continued to receive, notwithstanding the vigorous competition of the old journals, and the feverish emulation of a brood of new ones. We fear neither: our plan is so unique, so comprehensive and original, and our scientific and political departments so characteristic, that we hold a position apart from all antagonism, and fill a place that no other journal can possibly occupy. Though we deem it right frankly to express our convictions with respect to the peculiar excellences of the MEDICAL CIRCULAR, yet we desire that the Journal should speak for itself, and owe nothing either to our professions or our prejudices. It is natural that we should think it the best Medical Journal ever published, because we have resolved that it shall be and have tried to make it so. That it *is* so, is to be judged from the evidence of its own pages.

One of the chief advantages of the MEDICAL CIRCULAR consists in its being the most perfect reproduction of the scientific literature of Medicine that is now published. Under the heading

SPIRIT OF THE PERIODICALS,

the British Isles, Europe, and America are laid under contribution to provide us with their varied experience, and numerous periodicals are exhausted of their wealth to enrich our columns. We also make a point of collating together in one number as many articles as possible from various sources, so that our readers may have a complete view of the opinions that have been expressed within any given period upon any important or temporarily interesting disease. On the subject of *Glaucoma*, for example, we have reproduced, in a more or less copious form, the articles of Messrs BOWMAN, HANCOCK, HULKE, DIXON, and others—in short, every article that has been published on the subject in the periodicals. *Vesico-Vaginal Fistula*, as represented by Messrs BAKER BROWN, EDEN WATSON, Dr SIMPSON, &c., has been dealt with in a similar manner, without any bias as to peculiarities of doctrine or practice. So also with reference to *Resection of Joints*. It cannot, indeed, be denied by a careful reader of the journals, that the MEDICAL CIRCULAR is the only one that gives a complete and impartial representation of current scientific literature.

The explanation is easy. Each of the other journals is limited to its own connection or clique for its sources of interest and information; the MEDICAL CIRCULAR alone comprehends all the journals, and deals with their contents without prejudice or affection.

FOREIGN SCIENCE.

In addition to these sources of intelligence, we publish, with as much regularity as is attainable, *Translations* from foreign journals; taking care that none but the most important articles are thus reproduced. Thus, to quote only a few, we have given translations of lectures and articles on *Thoracentesis*, by M. ARAN; *Fractures in Children*, by M. GUERSANT; *General Palsy*, by M. BRIERRE DE BOISMONT; *the Expulsion of the Placenta*, by M. LIZÉ; *Laryngeal Phthisis*, by M. PIORRY; *Hepatic Colic*, by M. TROUSSEAU; *Disease of the Brain*, by M. BOUILLAUD; *Epidemic Dysentery*, by M. LERICHE; &c. &c.

To these departments must be added OUR NOTE BOOK, which gives the cream of the fugitive notices of science that appear in the numerous periodicals that come under our eye. Thus it is scarcely possible that any fact or statement of importance to science can be promulgated in any periodical without being at once reproduced in one or other of these departments.

ORIGINAL CONTRIBUTIONS.

We can point with equal pleasure to the original articles that have been contributed to this Journal during the year. Among these we may briefly enumerate the admirable practical Course of Lectures on the *Diseases of Women*, by Dr CHARLES WALLER, and the articles on *Diseases of the Skin*, by Dr ROSS, now in progress of publication; the ingenious dissertations on the *Sympathetic System*, by Dr RORIE; the Lectures on *Ophthalmic Diseases*, by Mr HAYNES WALTON; the valuable contributions on *Vesico-Vaginal Fistula*, by Mr BAKER BROWN; the copious papers on *Spermatorrhœa*, by Mr MILTON, and on the *Spinal Cord*, by Dr BURGESS; and the numerous Clinical and other Lectures by Messrs HILTON, STANLEY, SKEY, BOWMAN OWEN, HUXLEY, and Drs CARPENTER, PARKES, LANKESTER, &c. &c., which have successively appeared.

HOSPITAL REPORTS.

The excellent and graphic series of Hospital Reports, which also form a conspicuous department of the MEDICAL CIRCULAR, will bear favourable comparison with any that are published by other journals, whether as regards accuracy, saliency, or fulness of detail. Our REPORTS OF SOCIETIES, also, are not second to any in our contemporaries.

REVIEWS.

In the Reviewing department of the Journal, our readers are provided with an analytical criticism or descriptive exposition, as the character of the book may make necessary, of all the important works that are published, as well also of the various *brochures* which, though unassuming in size, frequently contain suggestions both new and valuable. It would be idle to attempt an enumeration of the numerous Treatises that have been reviewed during the year, but we may instance TODD on *Acute Diseases*, MARKHAM on *Diseases of the Chest*, WINSLOW on *Obscure Diseases of the Brain*, BRYANT on *Diseases of the Joints* and *Clinical Surgery*, PIRRIE'S *Surgery*, COMBE on the *Management of Infancy* and CHAVASSE'S *Advice to Mothers*, INMAN'S *New Theory of Medicine*, ACTON on *Diseases of the Urinary and Generative Organs*, SMITH on *Hæmorrhoids*, HABERSHON on *Mercury*, among many others.

EDITORIAL.

In our Editorial department, we have exercised the same vigilance over the interests of the Profession and maintained the same liberal principles which have from the beginning characterised the MEDICAL CIRCULAR. Some years ago we originated the idea of the establishment of COTTAGE HOSPITALS, and this year we have had the satisfaction to find our advocacy bearing fruit in the institution of such domestic charities in provincial districts. We hope to see, ere long, our original idea carried out in all its detail and amplitude. We have also been instrumental in raising a discussion on the merits of the stimulant method of treating disease,—known as the BRANDY controversy,—and, we believe, have been the means of recalling thinking men to

NOTICE.—This Number of the MEDICAL CIRCULAR is sent free to every Member of the Profession whose name appears in the 'Medical Directories.'

*** **The subjoined Form of Order applies only to Gentlemen NOT already Subscribers, who will have the goodness to fold it in the form of a Letter, with the Address outside, and return it to the Office.**

FORM OF ORDER.

To the Publisher.

Sir,

Please to send me the MEDICAL CIRCULAR weekly until countermanded.

Name _____

Address _____

Date _____

Post-office Orders to be drawn in favour of Thomas Rolfe, 20 *King William street, Strand, payable at the Branch Office, Charing cross.*

TERMS OF SUBSCRIPTION.

Annual, 19s. 6d. Single copy, 5d.; Stamped, 6d.

THE MEDICAL CIRCULAR,

And General Medical Advertiser,

PUBLISHED EVERY WEDNESDAY MORNING.

Price 5d.; Stamped, 6d. Annual Subscription, 19s. 6d.

The Medical Circular, on account of its cheapness, as well as the varied nature of its contents, has obtained a position unexampled in the history of Medical Periodical Literature. Being the only weekly *résumé* of the other Medical Journals, and containing Original Articles and Communications, brief but practical, it has become indispensable to the Medical Practitioner, and enjoys a large and influential circulation. It is, therefore, a most suitable medium for all Announcements addressed to the Medical Profession. Besides having a large surface size, it possesses a great advantage over its contemporaries, as the Advertisements are in all cases well displayed, and can hardly escape notice.

RELATIVE STAMPED CIRCULATION.

The following Return, being the last printed by order of the House of Commons, shows the Stamped Circulation during the six quarters as therein stated of the Medical Circular and 'Lancet:'—

MEDICAL CIRCULAR	103,900	**LANCET**	110,500

The Unstamped Circulation is probably in the same ratio. Approximating so closely to our old contemporary the 'Lancet, we may look forward to our future with confidence and satisfaction.

RELATIVE SCALE OF SUBSCRIPTION.

MEDICAL CIRCULAR	**£0 19 6**
LANCET	1 14 8
MEDICAL TIMES AND GAZETTE	1 14 8

TERMS FOR ADVERTISING IN THE MEDICAL CIRCULAR.

Six Lines and under	£0 3 6	One Column	£2 2 0
Per Line extra	0 0 6	Three Columns, or One Page	5 5 0

Advertisements should be delivered and paid for at the Office before Twelve o'clock on the Monday preceding publication; or if not paid for at the time, should be accompanied by a respectable reference.

Post-office Orders are to be made payable to Thomas Rolfe, 20 King William Street, Strand, London.

To the Publisher of

THE MEDICAL CIRCULAR,

20 KING WILLIAM STREET, STRAND, W.C.,

LONDON.

SAMPLE OF THE CONTENTS OF THE 'MEDICAL CIRCULAR,'

As shown during the Four Weeks of November.

NOVEMBER 7, 1860.

Scientific: — On Polypus Uteri. By Dr Waller. — Two Cases of Purpura Hæmorrhagica. By Dr Gason.—The Non-Digestion of Fat. By Dr E. Ancelet.—Cases of Placenta Prævia. By Dr Fleming.—Lecture. By Dr Brinton.—Two Cases of Concealed Accidental Uterine Hæmorrhage. By Mr H. James.—Recovery after Apparent Death by Chloroform. By Mr Broadbent.—Description of a Monster. By Mr Beale.—New Instrument for Vaccinating. By Mr Spratty.—Rupture of the Liver. By Dr M'Millan.—Turkish and Roman Baths. By Mr Wells.—Partial Turning. By Mr Sedgwick. —Transmission of Syphilis by Vaccination. By M. Viennois. — Protracted Natural Labour.—Two Cases of Paraplegia and Paralysis.—The Thermo-Electrical Bath. Dr Tucker.—Constipation.—Clinical Remarks on Tumours within the Cranium. By Dr Brown-Séquard.—Treatment of Epiplepsy. By Dr Brown-Séquard.—A severe Burn treated with Alum. By Dr Turner.—A New Operation for Amputation of the Foot. By Dr Smith.

General:— Case of Evan Thomas the Bonesetter, Poor-law Medical Reform Association, Medical News, Appointments for the Week; Births, Deaths, &c.; Notices to Correspondents, Pass Lists; Soldiers, Philosophers, and Beards; Female Industry.

NOVEMBER 14, 1860.

Scientific: — Pathology of the Sympathetic Nerves. By Dr Rorie.—On the Non-Digestion of Fat (continued).—On Sub-Maxillary Adenitis resulting from Dentition. By Dr Gouriet.—On Paralysis. By Dr Brown-Séquard.—On Pain. By Mr Hilton.—Fissure of Rectum. By Mr Le Gros Clark.—Medicine in China. By Dr Hobson.—On Fibroma, Typhoid Fever. By M. Aran.—Lingering Labour. By Dr Nelson.—Removal of Sequestrum.—Removal of Lower Jaw.—Removal of Tumour on Thigh.—Hemiplegia on Left Side.—Clinical Reports of Cases under the care of Mr Baker Brown.—Menorrhagia treated with Cream of Tartar.—Constipation treated with Colchicum. By Dr Bates.—Lupus. By Dr White.—Coffee in Delirium Tremens.—Bismuth in the Treatment of Burns. By Professor Richardson.—The Oil-Wells of Pennsylvania.—Linear Crushing and its Application to the Treatment of Hæmorrhoids. By M. Chassaignac.

General: — The Turkish and Roman Baths, Bad Times for Doctors, The Medical Society of London, More Arsenic-eating, The Medical Staff in China, The Editorship of the Association Journal, Reviews, News, Pass Lists; Births, Marriages, and Deaths; Appointments for the Week, Notices to Correspondents.

NOVEMBER 21, 1860.

Scientific:—Pelvic Inflammation and Abscess. By Dr Waller.—Pathology of the Sympathetic Nerves (continued).— On the Frequency of Morbid Alterations of the Uterine Appendages in cases said to be Uterine.—Diseases of the Kidney. By Dr Goodfellow.—Action of certain Substances upon Phthisis. By Dr Cotter.—Medicine in China (continued). — Eleven Cases of Vesico-Vaginal Fistulæ. By Mr Baker Brown.—What is commonly called Rigidity of the Os Uteri. By Dr Arnott.—Radical Cure of Inguinal Hernia. By Dr Aitchison. — Antagonistic Action of Opium and Belladonna.—Statistics of Diphtheria.—Constipation connected with Fibrous Tumour of the Uterus.—Resection of Elbow-joint. By Mr Erichsen.—Exploratory Operation upon Buttock of Right Side.—Fatty Tumour.—Malignant Tumour of Thigh.

General:—Medical Remuneration, Legal Intelligence, Medical Society of London, Letter of Dr Day, Testimonial to Mr Belfour, The Thames Embankment, Death by Fire, The Abolition of Newgate Market, The Apothecaries' Dinner, A Patent Way of Poisoning, Pass Lists, News; Births, Deaths, &c.; Appointments, Notices to Correspondents.

NOVEMBER 28, 1860.

Scientific:—The Parasitical Diseases of the Head and Face. By Dr G. Ross.—Certain Points connected with Diabetes. By Dr Pavy. —Eleven Cases of Vesico-Vaginal Fistulæ (continued).—Phthisis Pulmonalis. By Dr Richardson.—Scarlatina and some of its Sequelæ. By Dr Turner.—Diseases of the Kidney. By Dr Goodfellow.—Cases of Aneurism of the Thoracic Aorta. By Dr Egan.—Fibrous Polypus of the Base of the Skull. By Dr Moore. —Visit to Graefrath. By Dr Lee.—Clinical Reports of Cases under the care of Mr Baker Brown. —Removal of Necrosis from Head of Femur. By Mr Fergusson.—Removal of Breast. By Mr Wood.—Tracheotomy. By Mr Fergusson.—Carcinoma of Breast. By Mr Cock.—Excision of Elbow-joint. By Mr Hilton.—Amputation of Breast. By Mr Erichsen.—Cure of Hernia (New Mode). By Mr Thompson.—Removal of Tumour on Parotid Gland. By Mr Hewitt.—Epidemiological Society.—Glycerin Lotion.—Hypodermic Medication by Sulphate of Quinine. On Retention of Urine in the Fœtus, as a Cause of Obstructed Labour.

General: — Homœopathy, Hydropathy, and Mesmerism, in Relation to the Sciences; Ellis *v.* Kelly, The Powers of the Medical Council, A Market for Second-hand Diplomas, Death of Dr Wall of Dunmanway, Dr Maekesy and the Waterford Coroner, Death of Dr C. Coote, Death of James Howell, Legal Intelligence, Pass Lists, News; Births, Deaths, &c.; Appointments, Notices to Correspondents.

The Eighteenth Volume (No. 444) will commence January 2, 1861.

more moderate and reasonable principles of practice. We may observe here, that, following up our attacks on quacks and quackery, we exposed the pretensions of the Rev. HUGH REED, the Cancer-curer, and were the cause of his removal from his clerical duties. To arrest his medical practice is, we fear, beyond our power, so great is the difference in the internal administration of the two professions. The interests of our friends the POOR-LAW SURGEONS have also had our best consideration. Knowing the responsibilities of our position in connection with this question, we have been careful to examine every proposition relating to it with a single thought directed to the interests of all parties; so that, whilst the underpaid may receive justice, the moderately-paid shall have no cause of complaint. We yet hope to see a simple and useful measure of reform carried through Parliament.

We shall not expatiate further upon these topics, but occupy the little remaining space left to us with remarks on two or three points which, in the estimation of approving Correspondents, give us a pre-eminence over other journals. One says, "My time is so much occupied, that I am unable to wade through the columns of your contemporaries: and why should I, when I find everything worth reading in them carefully collated and reproduced in your valuable CIRCULAR? At the end of the year, too, I find that I have only half the subscription to pay which others demand." Another writes, "My Wednesday evening is the pleasantest I pass in the week; and I owe it to the MEDICAL CIRCULAR, which regularly arrives by the morning post. Shut out as I am from the great world, practising in this remote village, your Journal is a regular God-send to me, for without it I should know nothing of what is passing in my Profession. The sovereign I annually send you is the best investment I ever make."

Success so unequivocal stimulates us to renewed exertions not only in the improvement of the literary food we offer, but in the vehicle by which it is disseminated. Thus, in the new volume commencing January 2nd, the MEDICAL CIRCULAR will be printed on a thicker and better paper, and will be in no respect inferior to any one of our contemporaries.

DEGREES AND DIPLOMAS AT THE WAR-OFFICE.—The College of Physicians of Edinburgh has drawn up a memorial or protest, addressed to the Secretary at War, respecting an encroachment by that Minister on what were conceived to be the privileges and rights of Colleges. In the consideration of the qualifications of Candidates for the Army Medical Service, it is intimated that a preference will be shown for those who possess degrees in Medicine. This the Edinburgh College resents. It represents to the Minister that its Licentiates are worthy of equal consideration with University Graduates. We understand that Mr Secretary Herbert, having duly weighed the objections of the College, adheres to his opinion, and is not disposed to accord to Licentiates the same place in his esteem as Graduates.

SUMMARY OF THE WEEK.

THE LICENCE OF THE ROYAL COLLEGE OF PHYSICIANS.

When the Edinburgh College of Physicians opened its portals to the General Practitioners, it was angrily assailed by the London College, and by each of our contemporaries. We alone advised the latter institution to imitate the example of the Scotch College, and to liberalise its constitution. We assured it that it must necessarily come to this, and hoped that it would cease its recriminations and reform itself without delay. We gave this advice in no taunting spirit, but with a sincere desire to uphold the College, whilst we promoted the peace and dignity of the Profession. The College has since seen the wisdom of our advice, and is now about to grant its Licence under the terms of its new By-laws. The Apothecaries' Society is wroth, and threatens law; but it is understood that in the event of the Society prosecuting any of the new Licentiates, the College will defend them in order to maintain its rights. We heartily approve of this determination of the College. If it should be successful, of which we have no doubt, all the junior members of the Profession will obtain the Licence of this College, instead of the Certificate of the Hall, and there will soon be an end of an enforced corporate association with the trade in drugs. This result has been our undeviating aim, as the most important practical means of elevating the social character of the Profession.

THE 'MEDICAL DIRECTORY,' 1861.

In a few days, and for the first time, the three Medical Directories for England, Scotland, and Ireland will appear in one handsome volume, at a price but a trifle more than subscribers have hitherto paid for one 'Directory' only. This pecuniary advantage has been mainly brought about by the increased extent of patronage and support accorded to the work by the Profession and by the public. We have been favoured with a sight of an early copy, and we venture to say that the book, when published, will be held to be alike remarkable for its comprehensiveness, its cheapness, and its general utility—a book of which the Profession may be justly proud.

The amount and variety of information given are truly surprising. It contains a brief biographical memoir of every Practitioner, distinctly marking, as far as collegiate and honorary distinctions, appointments, and bibliographical productions can do, his status in the Profession. This feature alone would stamp it as an invaluable work of reference; but when we turn to its multitudinous subjects of information, extending to 1000 pages of closely-printed matter, all bearing on the Profession, it is impossible to over-estimate such a work, not only to every one whose name is enrolled in its pages, but to the public at large.

The 'Directory' has been not inaptly designated one of the bulwarks of the Profession; and if viewed in that light only, it well deserves the continued support and good wishes of every man whose name appears honourably in its pages. May it flourish for ever!

THE ROMAN BATH IN LONDON.

We are glad to find by a letter from Dr Tucker, of Sligo, printed in another column, that Dr Barter, the indefatigable promoter of the Roman Baths in Ireland, is about to act upon our suggestion, and is coming to London to establish one in our Metropolis. We heartily wish him success in his undertaking. We have no doubt, if it be carried out with spirit, with ample means, and on a liberal scale, that it will receive the patronage both of the Profession and the public. Most of the London Baths for the use of the better classes are conducted in a paltry style, and are more costly than the accommodation warrants. They are also incomplete in their arrangements for Medical purposes.

PUBLIC BANQUET TO DR COPLAND.

We last week adverted to a proposal to honour Dr Copland with some public testimony of the Profession's respect for his character and genius. We now publish a letter from Dr W. V. Pettigrew, who offers his services as Honorary Secretary in aid of efforts to organise a Public Banquet for this purpose. No doubt, a Committee will be speedily formed, and full consideration given to this proposal. Dr Copland is held in general esteem, and is deservedly regarded as the chief of British Medical literates. No more suitable period for this demonstration could be chosen than that afforded by the completion of the *magnum opus* of the redoubtable Doctor.

To the Editor of the Medical Circular.

SIR,—One of the most learned and practical works achieved by any Medical man in modern times is universally acknowledged to be Dr Copland's 'Medical Dictionary,' a work that has occupied the energetic attention and labour of the Author no less than thirty-two years. Why not show the public that we justly acknowledge and honour this ornament to our Profession? I would suggest that we invite Dr Copland to a Public Banquet; and I strenuously call upon my Medical brethren to assist in this undertaking, and shall be only too happy to take upon myself the onerous task of acting as Secretary.

I am, Sir, &c.,
W. VESALIUS PETTIGREW, M.D.
7 Chester street, Grosvenor place,
December 6th, 1860.

THE CASE OF EVAN THOMAS.

Some time since, Evan Thomas, a bone-setter, was committed for trial by the Birkenhead Magistrates on the charge of having caused the death of a boy named Francis Timlin by maltreatment. The child was suffering from an abscess of the thigh, which, it was alleged, Thomas mistook for a fracture, and accordingly bound it up with bandages and splints. The question was, whether the pyæmia which was observed after death had been caused by such treatment. Since then,

Evan Thomas has been tried at the Crown Court, Chester, before Mr Justice Blackburn, and has been acquitted. In the course of his charge to the Grand Jury the learned Judge said, "It appears that Thomas has not been regularly trained to the Medical Profession; *still* he practised as a bone-setter '*in the regular way.*'" What does Mr Justice Blackburn mean by 'the regular way?'

THE ELECTION OF A NEW EDITOR OF THE 'BRITISH MEDICAL JOURNAL.'

The election of Dr Markham as Editor of the 'British Medical Journal' is likely to prove another bone of contention to the peace-loving Members of the Association. A long protest against the dismissal of Dr Wynter has been sent to the Committee of Council by sixteen of the leading Metropolitan Members, no doubt personal friends of the late Editor,—and a reply has been returned by the Committee of Council—also numbering sixteen at the Meeting,—asserting their right to elect or dismiss, and affirming that they had sufficient grounds for their recent act of authority. Thus, the Metropolitan Sixteen and the Provincial Sixteen have had their first innings. The lookers-on are likely to see some fine play at the next Meeting. The Hull Members, on their part, protest against the appointment of a permanent Editor, as they desire to see the Journal abolished as a weekly periodical. We think these gentlemen have formed a judicious opinion. The Journal is utterly unworthy of the present state of Medical science and journalism, and has become to a considerable extent a vehicle for the lucubrations of second-rate Metropolitan Practitioners, who are anxious for the patronage of the Provincial Members of the Profession. The Association, with such a poor literary affair as its organ, never can attain the scientific status which it ought to enjoy, and which its Members are well qualified to confer upon it. The more numerous the Association, the more apparent and gigantic its failure. It is not creditable to British Physic, that two thousand well-educated men should be represented by so inferior a publication. For two or three years we have taken no notice of the Association or its Journal; and we now revert to the subject when one Editor is going out of office and another coming in, because at this juncture we cannot be charged with a desire to embarrass the Editor, whoever he may be, in the discharge of his difficult duties.

THE TITLE OF DOCTOR.

A most important opinion has been given by Mr Deasy, Her Majesty's Attorney-General for Ireland, with respect to the right of the King and Queen's College of Physicians to confer the degree of Doctor of Medicine. The point is not simply whether a Licentiate of the College can use the prefix "Doctor," but whether he is a full M.D. The opinion is as follows:

"The two Charters of the College, and the several Acts of Parliament bearing thereon, having been submitted to the Attorney-General, his opinion was requested on the following query:

"'Whether the Licentiates, as such, of the King and Queen's College, are entitled to the Degree and Title of Doctors in Medicine, and to use the abbreviation or initial letters M.D. after their names?'"

Answer.

"'I think the Licentiates and Fellows, as such, of the King and Queen's College of Physicians, are entitled to the Degree and Title of Doctors in Medicine, and to use the letters M.D. after their names. (Signed) "'R. DEASY.

"'November 21, 1860.'"

This opinion throws a new light upon this disputed question. We have been aware that the right of this particular College to confer the Doctorate has been always positively asserted; and we should like now to know whether, if the right be proved in this instance, it can be held to justify, by fair and reasonable inference, the same right assumed for the sister Colleges in England and Scotland.

HOMŒOPATHY IN CHELTENHAM.

The Homœopaths are now making an attempt to introduce their method of practice into the Cheltenham Hospital. They require one ward to be given up to them for their ministrations, and the Governors are about to be convened to decide upon the claim. Surely Cheltenham will not disgrace itself by giving public sanction to such an absurd system of empiricism. Common sense in relation to physic is in more danger in watering-places than elsewhere, but we trust that it has strength enough left, even in Cheltenham, to resent this insult.

HARVEY'S REMAINS.

It is reported that the College of Physicians are in communication with the descendants of Harvey, with the object of obtaining the removal of his revered remains to Westminster Abbey. The Profession will be gratified by the accomplishment of such an intention. Where could Harvey's dust lie so appropriately or honourably as next the ashes of John Hunter in our national Walhalla?

REVIEWS.

Chemistry in its Relations to Physiology and Medicine. By George E. Day, M.D., &c.

The rapid development of animal chemistry during the last few years has made it difficult for any ordinary student to master the multiplicity of details that constitute this branch of science. The connection between the several facts and their relations to states of health and disease are neither clearly comprehended nor remembered; and it unfortunately happens that so much theory is usually intermingled with every fresh increment of fact, so much ingenious hypothesis interwoven with every new exposition of function, that the mind is rather embarrassed than enlightened by the majority of essays upon this subject. The Profession was, therefore, in want of a clear and systematic exposition of this branch of science—an exposition that should not be encumbered with useless speculations, and that should convey all that was known or proved without being overlaid with conjecture and hypothetical explanations. Such a work Dr Day has now produced. The Author's acquaintance with the subject of physiological chemistry is not of yesterday; and, perhaps, there is no member so well acquainted as he with the labours of the French and German chemists in this department. His present work is a reproduction of the most advanced stage of German science. With such men as Lehmann, Scherer, Vogel, Frerichs, Bidder, and Schmidt—to whom must be added Robin and Verdeil—as his guides, we may feel assured that nothing is wanting to make Dr Day's book the most complete work of its kind in the language.

The work is divided into Three Books. After some introductory observations, the Author commences the detailed portion of his work with a description of the Non-nitrogenous Organic Acids, including the Fatty Acids, the Succinic-acid group, the Oleic-acid group, the Benzoic-acid group, the Lactic-acid group, and, lastly, the Non-nitrogenous Resinous Acids.

Next in order come the Nitrogenous Basic Bodies; following these, the Nitrogenous Conjugated Bodies; then the Haloid Bases and Salts, the Carbo-hydrates, the Animal Pigments, the Protein Bodies, the Proximate Derivatives of the Protein Bodies, and, finally, the Inorganic Constituents of the Animal Body. This ends the First Book.

The Second Book treats of the Chemistry of the Animal Juices and Tissues, commencing with the Digestive Fluids, then the Blood and its allies, followed up with the Fluids of Generation and Development, and the Secretions, Exudations, and Solid Tissues.

The Third Book treats of the Zoo-chemical Forces—the Metamorphosis of the Tissues, Digestion, Respiration, and Nutrition.

Such is a brief outline of the classification of subjects in Dr Day's work. It would be impossible to give a minute analysis of this valuable work; but in order that our readers may obtain an idea of the lucid and succinct mode in which the Author treats his subjects, we select some paragraphs from the article on Urea:

"Our information on the effect which diseases produce on the amount of urea is not very satisfactory. Heller observed the greatest quantity of urea in meningitis, the whole urine solidifying in a few minutes into a crystalline magma on the addition of concentrated nitric acid. According to the same observer, the urea is in excess during the stage of exudation, but diminishes during resorption, in pneumonia, in pleuritis, and in acute rheumatism, especially if endocarditis be simultaneously present: in the beginning of typhus there is an augmentation of the urea, but not so great as in the above-mentioned diseases. In most renal disorders, and in the chronic neuroses, there is a diminution of this constituent. Dr A. Vogel, in an excellent memoir 'On the Augmentation and Diminution of Urea in Diseases,' which is based upon 182 analyses, conducted according to Liebig's method, states that he found the largest amount, eighty grammes, in a case of pyæmia, and the next greatest quantity, sixty-nine grammes, in a case of typhus fever. It appears, from his investigations, that in typhus fever the excretion of urea is increased only so long as the febrile symptoms continue, and that when the fever is over the quantity of urea falls below the normal amount, notwithstanding the increased quantity of nitrogenous food. In Bright's disease (affecting both kidneys) the urea often falls to one-third or one-fourth of the normal quantity; and in polydipsia hysterica (although the amount of urine is very great) the total quantity of urea is much diminished. The smallest quantity observed by Vogel occurred in a case of carcinoma of the liver with great atrophy, when it was once found to fall below seven grammes.

"It is only recently that the presence of traces of urea in healthy blood has been satisfactorily established; the rapidity with which it is removed by the kidneys rendering its certain detection, even in five or six pounds of blood, by no means easy. It is abnormally increased in cases in which the functions of the kidneys are imperfectly executed, especially in Bright's disease, renal ischuria, and cholera.

"It is a normal constituent of the fluids of the eye (Millon, Wohler), and of the liquor amnii (Scherer).

"Urea has been in vain sought for in healthy muscular tissue, where, if the theory be correct that it is mainly formed by the disintegration of that structure, we should especially expect to find it. It has, however, been found by Buhl and Voit, and likewise by von Bibra, in considerable quantity in the muscular tissue of cholera patients. In one case von Bibra found 0·317% of urea in the dried tissue of the gluteal muscles.

"Whenever the urea is not duly separated by the kidneys we find it in most of the animal fluids, especially in the sweat and in serous exudations:

under these circumstances it likewise occurs in lesser quantity in the saliva, the bile, and vomited matters.

"It is well known that the origin of urea is still a *quæstio vexata* amongst chemists and physiologists; one party, including the names of Liebig, Bischoff, and others, holding that the urea is solely a product of the metamorphosis of the nitrogenous tissues; whilst the other party, which ranks amongst its supporters Lehmann, Frerichs, and (more especially) Bidder and Schmidt, maintain that the formation of urea is dependent upon two factors, one of which is variable, namely, the amount of assimilated histoplastic or albuminous food; while the other is constant, namely, the necessary consumption of the albuminous tissue when the animal is fasting.

"It admits of no doubt that urea is formed from the nitrogenous constituents of the organism, its artificial production from such substances affording the strongest evidence on that point: in addition to which we may add the facts observed by Lassaigne, Scherer, and others, of urea being contained in the urine excreted after nearly three weeks' starvation. As the metamorphosis of tissue occurs with the greatest activity in the muscular system, and as, further, increased bodily exercise augments the amount of urea, we are justified in regarding the urea as formed for the most part from the worn-out muscular fibres, although it is most probable that other vital tissues may contribute to the general amount. Whether it is formed in the organic particles at the moment of their disintegration, or whether it is first formed in the blood, is a point which cannot be considered as decisively established; but it is most probable that the latter is the correct view, because Liebig, in his experiments on large quantities of muscular juice, could not detect in it any trace of urea, although he found substances from which he could produce it artificially. It seems, therefore, almost certain that these substances (creatine, creatinine, and probably inosic acid) are decomposed in the blood, by the action of the alkalies and of free oxygen, into urea and other matters to be excreted. Moreover, the view that the urea is formed in the blood is supported by well-known experiments, showing that gelatin, glycine, alloxantin, theine, and other substances, which it is impossible to suppose can form tissue, are converted into urea and other matters, as is evidenced by the fact that this substance occurs in a perceptibly increased quantity in the urine, soon after any of the above-named substances have been swallowed.

"Lehmann's view that the urea is in part formed from assimilated nitrogenous food which has never entered into the substance of the tissues, is chiefly based on the following facts: (1) on the extent to which its amount is increased by the free use of animal food (nature in this way getting rid of the superfluous plastic material along with that which has become unfit for use; and (2) on the circumstance first noticed by Frerichs, but mainly established by the investigations of his opponent, Bischoff, that the use of gelatin and and gelatinous food so rapidly increases the quantity of urea, that we are compelled to believe that these nitrogenous matters are at once directly oxidised in the blood, without having entered into the composition of the tissues; and if these, why not the protein-bodies also? (We should observe that Bischoff himself fully grants that the gelatin is directly converted in the blood into urea, but, he adds, it is never a natural article of food, nor is it ever found as a normal constituent of the blood.)

"When treating of uric acid we shall show that in all probability a great part of the urea, separated by the kidneys from the blood, had previously existed in the form of that organic acid.

"Whether urea exerts any special influence on the fluids of the eye is a question that no one has yet attempted to answer."

It is with much pleasure that we recommend this work to our readers, who will find it an indispensable adjunct to their studies in the science of the Profession.

PARIS HOSPITALS.—In the annual budget of the city of Paris, charitable establishments figure for the amount of 9,319,078 francs of expenditure, being nearly the same sum as is annually expended in that city on the National Guard and Guard de Paris.

ANIMALS AND THEIR WANTS;

We should like somebody to write the biography of a Doctor's Horse. It would be an interesting story. Saddled or harnessed at half-past ten in the morning, he commences his daily round of duty, climbing steep hills, or trotting over broken roads, in wind, rain, or snow; taking a short nap while he stands, and knocking his nose against the gate-post at which he is tied; then home in the evening for his hay or corn—unbruised corn, we fear; out again at night for a cross-country excursion. Alas! poor horse! There is not much to choose between his trials and those of his master. Still, a country Doctor is generally fond of his horse, and treats him as well as Fate will let him. We are, therefore, glad to find that the claims of our useful dumb companions are not overlooked in this age of advancement and philanthropy, and that they have found a champion and friend in the person of Mr Thorley; and that, too, not a lean friendship, as every one who has visited the cattle show in Baker street will have perceived.

There are few, possibly, who read these remarks, who would like to eat their steak badly dressed, or without those additions in the shape of salt, mustard, and pepper, so grateful to the palate; and Mr Thorley maintains that suitable condiment is equally grateful to dumb creatures, and also that it is absolutely necessary to their health and comfort. Doubtless, in a state of nature, instinct directs them to these things, as it induces the horse to disturb the water before drinking. This is singularly shown in the fact that the mineral springs at Cheltenham were discovered by the flocks of pigeons which were attracted to them, possibly, on account of the salt they contained. But in the crowded city, cattle, like ourselves, live artificially, and require to be provided for accordingly.

We venture to think that this subject is not unworthy the notice and investigation of our readers, with whom the horse is an inseparable necessity; nor, we imagine, will any horse object at least to give the food in question a trial, as it is by no means ungrateful even to the human palate. It appears to have been carefully analysed by Dr Hassall, who remarks:

"First. That the ingredients used are all of excellent quality, and are purchased without regard to expense.

"Second. That the receipt or formula, according to which the food is prepared, is an admirable one, no ingredient being selected on account of its cheapness, but those only being chosen which are best adapted to fulfil the objects intended.

"Having regard, thus, to the composition of Thorley's Food for Cattle, I find that it possesses the following properties in an eminent degree: It is highly nutritious and fattening—it is a tonic and gentle stimulant, aiding, when mixed with other descriptions of food, materially the digestive powers of an animal; a point of great consequence, since it is an undoubted fact that much of the nourishment contained in the ordinary food given to cattle is lost in consequence of the impaired or defective action of the digestive organs."

Mr Thorley's urbanity will, we feel certain, secure any Medical Gentleman a sight over his extensive Mills in the Caledonian road, or provide further information as to the properties and advantage of using his preparations.

GENERAL CORRESPONDENCE.

THE LONDON LIFE-BATH.

To the Editor of the Medical Circular.

SIR,—Your important leading article on Roman or Turkish Baths of the 14th of November, in which you point out the superior scientific merits of these thermo-electrical baths, and suggest such a temple of health at the Crystal Palace, and in every town of any importance in the kingdom, has, it would seem, produced its influence upon Dr Barter, the founder and patentee of the new and improved form of hot-air baths, who is my companion in the Sligo Life-bath, which is just now being constructed here, and will be open in a few weeks. Dr Barter is resolved to act immediately upon your suggestion, to establish a first-class Roman or hot-air bath in London—one worthy of the city of Medical Science, and of the Medical Profession, of which he is an honourable and worthy member, and also of the Royal College of Surgeons, England. Mr Urquhart imported the bath idea from Turkey, and wrote a very eloquent work upon its merits, which remained unnoticed: "for nearly twenty years he (Mr Urquhart) had been labouring to get some one to carry out that system which was at once a mark of civilization and enlightenment among Eastern nations." His exertions had not the shadow of success until he received from Dr Barter an intimation that he would place land, workmen, and materials at his disposal. "When he (Mr Urquhart) stated that for twenty years he looked in vain for a man to make this experiment, he paid the highest compliment in his power to Dr Barter." The foregoing are words taken from Mr Urquhart's speech, delivered at Blarney, and reported in the 'Cork Constitution' of June 7, 1856. Dr Barter, who is a man of deep thought and practical mind, found himself beset with many difficulties in bringing this new project to perfection; he saw many defects and ample room for improvement, which obliged him to consult with an eminent engineer, and the result was the construction of a perfect hot-air bath upon the most improved scientific principles—the fruit of his own inventive genius—for which he obtained a patent, and under which he has already built baths in Dublin, Cork, Limerick, Blarney, Bray, Belfast, and Killarney, and is now building in Sligo and Waterford, and about to commence on the Curragh of Kildare—and, though last, not least, in London! a grand one. Dr Barter has accomplished in three years what the Emperors of Rome took three centuries to accomplish in that ancient city of five millions. While Dr Barter is reviving these ancient Roman baths in Ireland, and about to do so in London, it appears that others are exhuming them from the tombs of centuries in England—at Wroxeter, for example.

He is, therefore, worthy of the patronage and support of the Crown and Government, of the Medical Profession, and of the public generally. Dr Barter, after examining the remains of a Roman bath—one of those of ancient Britain—was enabled to introduce the mode of heating anciently used, and to abandon the Turkish innovation of admitting vapour; so that his patent life-bath is essentially the same as the Roman bath of ancient Britain. The great fact that 300,000! persons have taken these baths already with benefit to their health, establishes their fame as a vital necessary. I fully concur with Dr Barter in their beneficial influence in diseases of the lungs, heart, liver, kidneys, skin, &c. I believe that the frequency of sudden deaths from heart disease will be unknown amongst those who take the bath regularly; for "the skin is the safety-valve of the heart," and, indeed, of all the inner vital organs, provided it be kept clean and in healthy action. Invalids, of course, should take them under competent Medical advice. The Medical man, possessed by the one idea, drugs—who is so governed by the pride of his own intellect that he cannot bring himself to take a bath, or to study the subject—will have to yield to the pressure of public opinion when directed by the higher light of Medical Science. He should be governed by that scientific sentiment of yours, expressed some months since, "that disease is not to be cured by drugs alone, but by whatever influences the varied functions of the human frame." "We are on the threshold of great improvements." We should respect and observe the philosophy of that Divine precept, the physical virtue of personal purification by perspiration—"In the sweat of thy face shalt thou eat bread." The foregoing text would seem to be the first authority for this bath, the antiquity of which is unknown—antediluvian. In this life-bath we breathe caloric, the propelling power of all steam machinery, and circulate it in the blood, where it develops the life of the flesh—animal electricity, that vital agent of all which works within us, which is the source of animal heat, of psycho-

physical sensation, of all the electro-chemical functions that are in being in the laboratories of our animal life. Caloric stimulates and warms the animal body, expands and dilates the lungs, opens and ventilates the whole system, purifies the blood, kills all animal poisons, flushes off the whole cuticular sewerage of the citadel of life from within outwards. In the outer world, caloric and electricity seem to act and react upon, and reproduce each other, and magnetism, and light under favourable circumstances. The same thermo-electrical influences seem to be developed within us—probably light also, though it be invisible. The inner psycho-physical constitution of man—a duplicate or living testimony of two worlds, not to be divided—seems to be a magneto-electric and electro-magnetic steam-engine, which develops and circulates caloric, electricity, magnetism, invisible light, and steam—these grand vital, physical, chemical, and mechanical powers of man's machinery, which our immortal but imprisoned essence the Soul animates and commands. It is the noblest of Medical pursuits to teach our fellow-men self-knowledge, the letters of life, the alphabet of their own existence; how to prolong life in health, to extinguish maladies by physical education; to be the philosopher of Nature, to ask her questions, to interpret her replies; to study that book of books—Nature—for all other books are second-hand to Her; to look through Nature up to Nature's God, be her minister and not her master, and be also the right arm of the Church—make scientific truth subservient to Divine truth and to Divine laws, while we practise the pure patriotic poetry of Christian charity towards our fellow-men in their sufferings from disease. If one man were submerged in the sea, should we not risk our life to save him? But, when we see hundreds of human beings deluged in a sea of preventible disease, on the brink of the ocean of eternity, is it not a glorious mission to try and teach them how to save and to prolong their lives? In the former case we take one man out of the water, in the latter we provide the means—the Life-bath—to take the water out of many men—by profuse perspiration—and thus remove those peccant humours that drown them in disease. It was such glorious work that induced Hippocrates to decline royal honours and favours from an Eastern king, rather than desert his fellow-countrymen in time of pestilence, and said to the Ambassador—

"Tell him that these pageants of King
Can never to my heart such raptures bring
As those I feel when, as I journey on,
Some pale youth from the wayside stone
Rises recovered, and, with arms outspread,
Calls down bliss on my unworthy head."

These are the noble works that call forth the Scripture words of Ecclesiasticus: "Honour the physician for the need thou hast of him, for the Most High hath created him."

I am, &c., J. Tucker, M.D.

Sligo, Dec. 6, 1860.

SCOTTISH MEDICAL GRIEVANCES AND THE 'MEDICAL TIMES.'

To the Editor of the Medical Circular.

Sir,—It is curious to observe the inconsistencies and vacillations of mankind. As an instance, on Saturday last, the 8th inst., the Editor of the 'Medical Times and Gazette' produced a really good article on "Two Scottish Medical Grievances;" but, *cui bono?* for unfortunately it has appeared too late to afford any benefit to the Profession in Scotland. Had such an article been written nine months ago, when we were struggling, by petitioning Parliament and other legal means, to obtain redress from the insulting penal clause of the Medical Registration Act (Scotland), it possibly might have been serviceable. Instead, however, of affording us assistance at the proper time, the aforesaid Editor treated our complaints in a somewhat cavilling manner, as may be seen from the following extract:—"After a second perusal of the Circular of the 'Glasgow Faculty of Medicine to the Profession,' we are quite at a loss to understand it. The Glasgow Faculty are not at all singular in having to send certificates of the cause of death to the Registrar free of charge. There is no such 'invidious distinction between him and his co-practitioners in England,' as the Society called the 'Glasgow Faculty of Medicine' seem to imagine." (See 'Med. Times' of March 24th, 1860, page 307.) Mr Editor must have greatly modified his opinions since he wrote the above quotation; for it strikes me, Sir, most forcibly, that if the Circular of the 'Glasgow Faculty of Medicine,' which was circulated in the same month of March, and for which the Faculty merits the deepest gratitude of the Profession in Scotland, were compared with the above-mentioned leading article, the latter would be deemed by any unprejudiced person as a reflex of the former in many of the arguments. At the time, I considered the Editor of the 'Times and Gazette' treated us rather scurvily, and I must confess my astonishment on perusing his manifesto of last week in our favour: indeed, it seemed a wonderful change for the better! Let us hope he will keep in the right path, and attend to the true interests of the Profession, instead of opening his columns to so many unprofitable debates on Medical Titles.

M.D.

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.

Dec. 8th.—Lithotrity—Removal of Enlarged Tonsils—Necrosis of Tibia—Resection of Elbow-joint.—Mr Fergusson. Necrosis of Head of Tibia.—Mr Bowman.

Lithotomy.

We described the first operation performed last Saturday by Mr Fergusson upon this patient. He was again, to-day, placed under the influence of chloroform. The proceedings incident to the introduction of the lithotrites were very interesting, and highly instructive. The facility of sounding and of breaking the larger fragments by the advance of the rack-blade of the lithotrite in the palm of the right hand, conveying leverage upon the lithotrite crusher under entire tactile guidance, left no room for hesitation, delay, or doubt. Two or three rapid rotatory movements at the distal extremity of the lithotrite sounded and discovered the fragment, and the advanced movements of the anterior blades by means of the rack held in the palm of the hand secured it. If not too large, it was directly brought away with a free and facile movement, between the blades of the lithotrite scoop. The rapid introduction of the lithotrite four or five times left nothing further to be done, and we believe the bladder was cleared of every fragment. Mr Fergusson dwelt on the advantage and success of this plan of immediate removal in preference to so-called spontaneous expulsion, or removal at different periods by injecting warm water into the bladder. All irritation from fragments remaining a longer or shorter period in the bladder after being broken down was avoided. He said, in elucidating the advantage of our present instruments and practice, that many years ago Sir Astley Cooper very justly gained great approbation for discovering an instrument to remove calculi from the bladder through the urethra; but it was not constructed so as to be able to break the stone in the bladder, as in the case of these instruments, to a suitable size fit for extraction. This triumph was left for lithotrity to accomplish. In the subject operated upon to-day, a very favourable case was witnessed. This patient, Mr Fergusson said, would be very easily relieved from his long sufferings, and cure be effected without resorting to lithotomy, or, indeed, to any painful process, since under chloroform he experienced no pain, and would be speedily quite restored to health.

Mr Fergusson said he had recommended lithotrity in this case, as he believed the stone to be small, the patient a good subject, and there existing an entire freedom of the parts from disease.

Enlarged Tonsils.

Mr Fergusson removed a considerable portion of hypertrophied growth with a cutting forceps which he recommends and uses for the purpose. Were Mr Fergusson to see the facility and precision with which an enlarged tonsil is removed by Mr Yearsley with his knife and forceps, we think that gentleman's procedure would be preferred to the method adopted on this occasion.

Necrosis of Tibia.

This patient, a girl about sixteen years of age, had been afflicted a long time with diseased tibia. It commenced with abscess forming under the periosteum, and destroying it: in consequence, the tibia, on its anterior aspect at the upper third, became necrosed. This condition had existed for a long time, and a considerable thickness of new bone had formed over the dead bone. The removal of the necrosed bone required the pincers to be applied for that purpose with considerable force, from the hardness of the bone. To effect this, Mr Fergusson enlarged the open ulcer which existed over the diseased bone, and gonged away portions of detritus and caries cold applications being applied to the wound.

Resection of Elbow-joint.

This patient had suffered from extensive disease of elbow-joint for seven years, and anchylosis had formed, with a straight arm. Some time since, from the stiff and unuseful condition of the limb, Mr Fergusson endeavoured, under chloroform, to obtain a better position of the joint, which he accomplished by its flexion at nearly a right angle. The patient went on well, and left the hospital. After a time the arm became neglected, and resumed its straight and awkward position. Mr Fergusson proposed to-day, by resection, to induce formation of a false joint. He made a longitudinal incision on the inner aspect of the joint, in the line of the ulnar nerve. This he easily removed on one side, but said he believed that it was not of much importance if divided. He then cut into the joint, the cartilages of which he found entirely destroyed by disease. With a small saw, the olecranon, with the extremities of the condyloid process of the humerus and a small portion of the head of the radius, were removed. In removing these portions of bone, some careful dissection was required, in consequence of anchylosis of the olecranon with the humerus being only partially effected, and fibrous exudation having completed the connection. Mr Fergusson remarked that this was one of those cases in which spontaneous cure was going on, and he had no doubt that, in time, a spontaneous cure might have been effected. This process would have required patience and long suffering; and although a cure would be ultimately obtained, it would be a bad cure and an unuseful limb. He therefore thought it better to recommend this operation, by which means a false joint would be formed, and a good limb preserved, by fibrous union.

Necrosis of Head of Tibia.

This patient, a child about eight or ten years old, was placed under the influence of chloroform. Disease had been in existence for five years. It was a case in which originally abscess had formed in the sheath of the muscles at the upper extremity of the tibia, and had travelled to a considerable distance, and several sinuses had formed upon the anterior aspect of the shaft of the bone. The tibia had in consequence become necrosed; but sinuses existed at a great distance, in consequence, from the seat of the disease. Mr Bowman made an incision down to the bone at the upper sinus, and removed portions of dead bone. He advised, in these cases, to make the incisions as small and as few as possible. Mr Bowman said, in these emaciated, worn-out subjects, it was a great object to avoid a large incision upon the hard bone, since great irritation and discharge were frequently the results, to the danger of the patient or delay of the cure.

ST GEORGE'S HOSPITAL, Dec. 13.

Removal of Large Fatty Tumour on Hip-joint.—Removal of Sebaceous Tumour on Face.—Mr Tatum.

Fatty Tumour.

This patient, a man sixty years of age, had a tumour formed on the gluteal aspect of the hip-joint, of large dimensions. It had existed twenty-five years, during which it had acquired this immense size. It was pendulous, and had a distinct neck. Under chloroform, Mr Tatum removed this tumour in the usual way.

Encysted Sebaceous Tumour.

This patient, a young man about twenty years of age, had a sebaceous tumour on the submaxillary bone, under the orbit. Two days before, an incision was made into it, when a serous fluid escaped. Upon making a longitudinal incision, a portion only of the tumour was dissected round and removed. Mr Tatum said it was not necessary to trace the connections of the cyst, which ran deeply into the sub-cutaneous tissues. He applied lint dressings soaked in a solution of sulphate of copper, which, he said, would induce healthy granulations to be produced at the bottom of the cyst, and fill up the wound. A case similarly treated had, a few days since, left the hospital cured. Chloroform was not administered in this case.

OUR NOTE BOOK.

ON THE ESTIMATION OF SUGAR IN DIABETIC URINE BY THE LOSS OF DENSITY AFTER FERMENTATION.

Dr William Roberts says: — When a diabetic urine is fermented with yeast, its specific gravity, previously ranging from 1030 to 1050, falls to 1009 or 1002, or even below 1000. This result is mostly due to the destruction of the sugar it contained, but partly, also, to the generation of alcohol, and its presence in the fermented product. As the diminution of density must be proportional to the quantity of sugar broken up by the ferment, the amount of loss evidently supplies a means of calculating how much sugar any urine contains, always provided that the remaining ingredients of the urine continue unchanged, or become changed in some uniform ratio.

To ascertain the relation between the density lost on fermentation and the sugar destroyed, experiments were made on the urine of diabetic patients on the following plan:—1. The amount of sugar per 100 parts was ascertained by the volumetrical method, with Fehling's test solution. 2. The density of the urine was taken. 3. Three or four ounces were then placed in a 12-oz. phial, with a drachm or two of German yeast, and having lightly covered the bottle, it was set aside to ferment. 4. In about twenty-four hours the fermentation was finished and the froth dissipated. The density was then taken a second time, and the loss calculated.

By operating in this way on a specimen of diabetic urine, sp. gr. 1038·60, the following results were obtained:—Sugar, per 100 parts, by the volumetrical method, 7·69; density before fermentation at 60° or D = 1038·60; density after fermentation at 60° or D′ = 1005·92: density lost, or D — D′ = 32·68.

The relation, therefore, between the density lost and the percentage of sugar in this instance was as 32·68 to 7·69, or as 1 to 0·235. By numerous trials with diabetic urines, of different strength, it was found that the most correct proportion was as 1 to 0·230. The corresponding formula, therefore, was:—

Sugar, per 100 parts, or S = (D — D′) × 0·23.

The accuracy of this method was further tested by operating on diabetic urine diluted with known volumes of water or non-saccharine urine, and on solutions of loaf-sugar in water and in healthy urine.

This method of estimating sugar is especially applicable to medical practice; and the following simple and most convenient rule expresses the result of the analysis:—*Each degree of "density lost" indicates one grain of sugar per fluid ounce of urine.*—'Transactions of Manchester Philosophical Society.'

ACCOUNT OF THE POISONING OF THENARD BY CORROSIVE SUBLIMATE.

M. Flourens read an interesting Eloge on Thenard, before the Academy of Sciences, January 30, 1860. We find in it the following account of the *sang-froid* of Thenard, when he had accidentally taken a large quantity of corrosive sublimate, and of the excitement incident to the occasion:

"During a lecture at the Polytechnic School, it happened, one day, that something necessary for the demonstration was wanting. Thenard called for it impatiently, and while the assistant ran with all his might to procure it, the Professor, by way of passing the time, put his hand on a tumbler and raised it to his lips without examination. Having taken two swallows, he placed it on the table. 'Gentlemen,' he said with *sang-froid*, 'I have poisoned myself.' An electric shock was immediately felt, and the faces of all became pale. Thenard stated that it was corrosive sublimate which he had swallowed, adding, 'White of egg will combat its effects: will some one get me some eggs? Scarcely had this sentence escaped him, when the doors and windows were not wide enough—they ran, they pitched headlong; the storehouses are forced open, the kitchens likewise—but no eggs: the neighbourhood, being put under contribution, was soon pillaged; each brought his share, and a mountain of eggs was reared. In the mean time a student flew to the Faculty of Medicine. Interrupting an examination, he cried: 'A doctor! Thenard has poisoned himself in the school while delivering his lecture.' Dupuytren arose. 'Do you understand?' he said, and ran out; a cabriolet is in the way—he mounts—whips the horses—arrives—leaps to the ground. However, thanks to the albumen, Thenard was already saved; but Dupuytren required the employment of the pump, so as to be sure that the stomach might not absorb any corrosive substance. The organ becomes inflamed, and, safe from the poison, Thenard is put in danger by the remedy."

"Thenard was carried home. There, all the doors were guarded; the students of all the schools united to surround the house with triple ramparts; advance sentinels were detached to keep off the troublesome; silent and mournful all awaited the news transmitted from within, where the most fitted were scarcely able to restrain their zeal: in the sincerity of their affection, they envied the privileges of the family. Day and night watch was kept without intermission, without fatigue, for this man, who swayed the whole realm of kindness, was the property of the youth, and they wished to save him. Every morning, accurate bulletins were affixed on all the large establishments; no one knew their authors. When Thenard reappeared in his chair at the Sorbonne, the excitement was so great that every one ran out without knowing precisely what he was doing; the Professor himself declared that he had no power of controlling his deep emotion."—L. H. S., in 'American Medical Monthly.'

Births, Marriages, and Deaths.

BIRTHS.

BRISTOWE.—December 9, at St Thomas's street, Southwark, the wife of J. S. Bristowe, M.D., of a daughter.

BRYANT.—December 3, at Clarendon House, Stewkley, the wife of Charles Bryant, Esq., M.R.C.S., of a son.

ELLIS.—December 4, at Colston parade, Bristol, the wife of R. W. Ellis, Esq., M.R.C.S., of a son.

PATERSON.—November 30, at Balbeggie, Perthshire, the wife of George K. H. Paterson, Surgeon, &c., of a daughter.

THANE.—November 21, at Park-place villas, Maida hill West, Paddington, the wife of W. D. Thane, Esq., M.R.C.S., of a daughter, still-born.

MARRIAGE.

BARNES—SMYTH.—December 11, at St Mark's Church, Regent's park, Dr George Barnes, of Newcastle, Staffordshire, to Elizabeth Frances, widow of the late Rev. B. S. T. Smyth, Incumbent of West Pinchbeck, second daughter of Thomas Bridges, Esq., of Marwood hill, North Devon, and niece of B. M. Wilcox, Esq., M.P. for Southampton.

DEATHS.

ANDERSON.—November 26, of fever, at Madeira, George Anderson, of Farnham, Surrey, Surgeon to H.M. Emigration Commissioners, aged 58.

BROUSSAIS.—December 1, of endocarditis, Dr François Broussais, last surviving son of the celebrated Broussais. He was himself author of many articles in the Medical periodicals.

CUMPSTONE.—November 30, John Cumpstone, of Market Rasen, Lincolnshire, L.S.A. Lond., aged 63.

GATES.—December 2, George John Gates, formerly of Northampton, aged 40.

GRANT.—December 6, suddenly, at Devonport, James Simpson Grant, of Durievale, Fifeshire, M.D., Surgeon 53rd Regiment.

HUNTER.—November 30, at Fermanagh, George Hunter, Lic. and L.M., R.C.S. Ire.

KEMP.—December 3, at Hamburg, Robert Horne Kemp, aged 38.

LANGSFORD.—December 8, after a short illness, Mr George Johnstone Langsford, of Hart hill, near Nuneaton, aged 38.

NUGENT. — December 6, Richard Nugent, L.K.Q.C.P. Dub., F.R.C.S. Eng., L.S.A. Lond., aged 42.

OWEN.—December 2, John Underhill Owen, of Landport, Portsmouth, M.D. Univ. Glasg., M.R.C.S. Eng., M.R.I.A., aged 53.

ROWELL.—August 20, Charles Rowell, late of Langtoft, Assistant-Surgeon in the Hospital ship 'Lancashire Witch,' in the Gulf of Pechili, China, aged 27.

SHARP.—December 4, Christopher Sharp, of Oldham, Lancashire, M.R.C.S. Eng., L.S.A. Lond., aged 26.

SIMPSON.—November 27, at Brompton, J. W. Simpson, late of the Medical Staff, Malta.

WALL—November 27, Robert Wall, of Dunmanway, Co. Cork, M.R.C.S. Eng., aged 39.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, Dec. 6th, 1860:—John Christopher Armstrong, Gravesend; Edwaad Olive, Hellingley, Sussex; William Pitt, Willinghall, Staffordshire; Daniel Seaton, Chester; Edward Alfred Tyler, High street, Marylebone. The following gentlemen also on the same day passed their first examination:—Francis Agget, Drewsteynton, Devon; James Bendall, Trowbridge, Wilts; Herbert Cooper, Richmond terrace, Clifton; Daniel Gibson, Waverley street, Hull; George Harrison, juna., Grosvenor street, W.; William Lockwood, Gloucester st., W.C.; Thomas Newby, London Hospital; William Payne, Walingford, Berks; William James Tyrrell, King's College.

APPOINTMENTS.—At a Special General Court, held on the 6th inst., Mr Alfred Winkfield, M.R.C.S. and L.S.A., of St Bartholomew's Hospital, was elected House-Surgeon to the Radcliffe Infirmary, Oxford, in the room of Dr Gray, resigned.—Mr Jonathan Hutchinson has been appointed Joint Lecturer on Surgery at the London Hospital Medical College.—At a meeting of the Dispensary and House Committees, held on Tuesday in the Board-room of Barrington's Hospital, Limerick, Stephen M'Mahon, M.D., was unanimously nominated to the offices of Medical Officer to the Dispensary and to Barrington's Hospital, in room of Dr M. V. Bourke, resigned.

GLASGOW SOUTHERN MEDICAL SOCIETY.—At the sixteenth annual meeting of this Society, held on the 6th inst., the following gentlemen were elected office-bearers for the ensuing year:—*President:* Mr Bryce Rankin.—*Vice-President:* Dr Henry Dunbar.—*Treasurer:* Dr H. R. Howatt.—*Secretary:* Mr Edward M'Millan.—*Seal Keeper:* Dr James Stewart.—*Court Medical:* Dr Peter Stewart (Convener); Dr H. R. Howatt; Dr Jas. Morton; Dr James D. Newman.—*Officer:* Thomas Robertson.

IRISH PATHOLOGICAL SOCIETY MEDAL.—The subject selected for the gold medal of the Pathological Society of Ireland, to be awarded at the close of the ensuing session, is, "The Diagnosis and Pathology of Diseases of the Spermatic Cord, and of the Testicle and its Coverings."

MILITIA MEDICAL OFFICERS.—It has been notified by the Secretary of State for War, in reply to the memorial of the Surgeons and Assistant-Surgeons of Militia Regiments, that commissions will be given to them in the Line, provided they *pass the necessary examination.*

APPOINTMENTS FOR THE WEEK.

Wednesday, December 19.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, December 20.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Surgical Home.—2 p.m.

LINNÆAN SOCIETY.—Dr T. Spence Cobbold, "On Animal Parasites (Entozoa), with Experiments," 8 p.m.

CHARING-CROSS HOSPITAL MEDICAL SOCIETY.—Dr Hyde Salter, "On the Stethoscope," 8½ p.m.

Friday, December 21.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON.—Practical Evening for the Narration of Cases and Exhibition of Specimens.—Mr Leggatt, "On a Case of Acute Glossitis," 8 p.m.

Saturday, December 22.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, December 24.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.

MEDICAL SOCIETY OF LONDON.—8½ p.m.

BOOKS RECEIVED FOR REVIEW.

Physiological Chemistry. By E. Day, M.D., &c.

Practical Means for Preventing Adulteration. By H. Letheby, M.B. London: M. Lewands.

On Diphtheria. By Edwd. H. Greenhow, M.D. London: John W. Parker and Son, West Strand.

Introductory Address. By J. H. Wharton, F.R.C.S.I.

Epitome of Surgery. By J. Beadnell Gill, M.D London: H. Baillière.

On Hospital Accommodation in Manufacturing and Mining Districts. By Mr John Robertson.
Gonorrhœa and Gleet. By Thomas Weeden Cooke. London: Henry Renshaw.
Food Collection in the South Kensington Museum. By E. Lankester, M.D., F.R.S. Fifth Edition. London: Her Majesty's Stationery Office.

NOTICES TO CORRESPONDENTS.

VERUS, commenting upon a notice in our last Number, relating to the fine imposed by the Court of Common Pleas on Dr Clarke, of Staines, suggests that it must have been solely owing to his sending the woman to the workhouse, which was done in an illegal and unauthorised manner. We have no doubt of this; in fact, this was the charge. At the same time, it is necessary to caution Medical men against falling into the same mistake. Insane persons who are *not* "dangerous," are not infrequently sent to the workhouse to be protected. If so doing be illegal, we fear that the illegality is very general.

Mr S. BROWN.—1st. Yes.—2nd. Yes.

CHIRURGUS.—The use of a current of electricity in lead poisoning was first resorted to by M. Briquet about two years ago. He believed it to have a specific effect in arresting the pain and eliminating the lead. M. Becquerel's views are more moderate: he denies that a current of electricity can remove the lead from the system, though it will relieve the spasm and pain.

Dr WILLIAMS is thanked.

AN OLD SUBSCRIBER (Plymouth).—The Numbers shall be forwarded.

H. S.—Your objects may be attained by application to Mr Moore, Ship Agent, of Tower hill.

Mr WM. B.—Newspaper; with enclosures, received.

ERINENSIS, on the Medical Council, received. The subject will be soon resumed.

A CURE FOR SNORING.

To the Editor of the Medical Circular.

SIR,—I would feel greatly obliged to you for any information you could possibly give me on the subject of *snoring*, in the hope of preventing or alleviating it, as my health is suffering from the unmitigated snoring of my wife. An unfortunate Medico, after nights of such interruption, is after some time made to feel the effect of the disturbance during his daily employment. I think that, being one of your oldest supporters, you will allow me to trouble you on the subject. H. W. N.

[Not knowing any effectual remedy for the unfortunate domestic affliction to which our correspondent is subject, and which, we fear, is of an epidemic character, we invite our readers to favour him with their experience. We venture to believe that the man who may devise a cure for snoring, and patent the invention, will rapidly make his fortune. What would be the result if our correspondent should adopt the homœopathic principle—*similia similibus curantur*—and snore too?—ED.]

A PROVINCIAL SUBSCRIBER.—The non-existence of a written contract to pay the bill is of no consequence, if you can bring forward witnesses to prove that the master either agreed to pay you, or requested your attendance, and was aware of it during the time. Otherwise a master is not bound to pay his servant's account. An implied pledge to you is not sufficient evidence.

Dr MACDONALD.—We are obliged by your note.

AN ASSOCIATE.—We have not expressed an opinion on Dr Markham's capabilities for his new office. We wish him good luck and good temper.

ST BARTHOLOMEW. — The vaccination fee is, no doubt, an unjustifiable tax upon the student, for the benefit of the public. You and your fellow-pupils should sign the Memorial we published last week.

Mr MCCLELLAND is thanked for his note: his suggestion, however, has come too late to be of use for this volume.

UNREGISTERED PRACTITIONERS.

To the Editor of the Medical Circular.

SIR,—Whilst Medical Practitioners are lamenting the incongruities of the Medical Act, they should make full use of the advantages left to them. I believe no unregistered person could successfully carry on an Apothecary's practice, if the public were fully made aware that no unregistered person could demand payments for medicines or attendance. Many years ago I lived with a Scotch Surgeon in London as his assistant. He used to visit and supply medicines, as an Apothecary might. He sent in his Christmas bills to the amount of nearly 400*l.* a year. People paid their bills, not doubting but that he had a legal right to the money. Had they been aware that he had no right in law, not one-third of them would have paid him.

I therefore propose (and here is work for Secretaries of Registration Societies), that, by paragraphs in newspapers, advertisements, &c., the public should be told that unless the party they employ is registered, either for Medicine or Surgery, as the case may be, they need not pay a farthing of their bills. I am, &c.,

A REGISTERED PRACTITIONER.

Dec. 8th, 1860.

Dr TUCKER.—Received and inserted.

Mr PATERSSEN.—Received.

A CONSTANT SUBSCRIBER.—1st. Apply at the Admiralty.—2nd. Yes.

Dr MILLMAN.—Too much must not be expected from our contemporary, who is apt to be bewildered on important questions.

Messrs LEECH and GWYTHER.—We are obliged by your note.

Mr S. W. SMITH's interesting communication shall be inserted.

ALPHA.—The signature of M.D. is not *illegal*.

COUNTY-COURT DECISIONS.

To the Editor of the Medical Circular.

SIR,—I scarcely know whether I ought to apologise for writing concerning County-Court decisions, but really they are a subject of great importance to the Profession. Perhaps the two following cases may show the necessity for some protest against such injustice.

Some three or four years since, I attended a woman with choleraic diarrhœa, incessant vomiting, spasms, with lividity and coldness of surface, &c. I attended eight days. The person resided, according to their own measurement, half-a-mile and 140 yards from my house. My claim was, for medicines, 1*l.*; for eight visits, 12s.: in all, 1*l.* 12s. A few months since I put it in the County Court in this town, and Sir Walter Riddell said that he considered 3s. a day amply sufficient for medicines and attendance. I consequently received the sovereign for medicines, and the munificent remuneration of 6d. a visit

In another case, I tried to recover a bill that had been outstanding five years. I swore positively that I had not received it; the defendant swore he had paid it. I asked for the receipt; he said he had lost it: he had no witness to the payment. The judgment was in his favour, as the Deputy-Judge thought he was more likely to remember paying me than I was to recollect not being paid at such a length of time.

I am, Sir, &c.,

H. SCHOLFIELD JOHNSON, M.D.

Stoke-upon-Trent, Dec. 10, 1860.

M.D. EDIN.—None but Graduates of Universities are equitably entitled to the affix of M.D. and the prefix of Doctor. Fellows and Licentiates of the Colleges of Physicians are entitled to the prefix of Doctor by courtesy and legally; but it is a stretch of their prerogative, and contrary to etiquette, to affix the M.D. to their names. The same remark applies to Bachelors of Medicine.

C. H. N.'s letter on "Poor-law Medical Officers and their Grievances" shall appear as early as possible.

Mr R. D. (Yorkshire).—Next week.

Mr J. GELL.—1st. He would not be eligible.—2nd. We think not.—3rd. We do not think that the College would interfere; though it would be contrary to their By-Laws.

Mr SANDERS is thanked; but we have no room for the Report this week.

Thorley's Illustrated FARMERS' ALMANACK, 77 NEWGATE STREET, CITY. This Sixpenny-worth contains more valuable information to the Farmer than any other almanack at even double the price, and ought to be on every Agriculturist's Book Shelf throughout the Kingdom.

Thorley's Agricultural GLEANER. — This Weekly is published every Saturday, and contains everything new and beneficial to the Agriculturist. Price 2d., Stamped 3d.—77 Newgate street, City.

Now ready, price 5s. 6d.,
or free by post to any part of the United Kingdom, price 6s.
Fourth Edition, greatly enlarged and improved.

A Grammatical Introduction to the LONDON PHARMACOPŒIA, and a KEY to PHYSICIANS' PRESCRIPTIONS. By S. F. LEACH.

"This little work will be found extremely useful to students who have received but an imperfect classical education."—'The Lancet.'

Hughes and Butler, Medical Booksellers and Publishers, 15 St Martin's-le-Grand.

Twickenham House.—Dr DIAMOND (for nine years Superintendent to the Female Department of the Surrey County Asylum) has arranged the above commodious residence, with its extensive grounds, for the RECEPTION of LADIES mentally afflicted, who will be under his immediate superintendence, and reside with his family. For terms, &c., apply to Dr Diamond, Twickenham House, S.W.

NOTICE Letts's MEDICAL DIARY, arranged for Vaccinations, Accouchments, Nurses' Addresses, &c., Patients' Names with column for Daily Visits. Neatly bound in cloth, pocket book, flap, pencil, and clasp, 2s.; French Morocco Tuck, two pockets and pencil, gilt edges, 3s.; best Pocket Morocco or Russia Book, 10s. 6d.; with divisions for instruments, 17s. and 18s. (Double the substance, 1s. 6d. extra.) Instrument Cases for ditto, 4s. 6d.

The other Editions of LETTS'S DIARIES commonly used by MEDICAL MEN, are Nos. 1, 2, 5, 9, 10, 12, 14; the Professional Appointment Diary; the Monthly Professional Diaries: Medical Visiting Lists, etc.

LETTS'S READING EASEL for INVALIDS, from 20s. to 40s. Sold by all Booksellers.—Fully descriptive catalogues gratis.

LETTS, SON, and Co., STATIONERS, 8 Royal Exchange, London, E.C.

Washing and Drying MACHINERY.

WILLIAMSON'S PATENT MACHINES are in use at numerous Hospitals, Workhouses, Schools, and Private Establishments.—Can be seen in operation (daily) at WILLIAMSON'S, PATENTEE & MANUFACTURER, 133 HIGH HOLBORN.—Illustrated Lists free by post.

Allen's Port- MANTEAUS and TRAVELLING BAGS, with square openings.

LADIES' DRESS TRUNKS. DRESSING BAGS, with silver fittings.

DESPATCH BOXES, WRITING and DRESSING CASES, and 500 other articles for home or continental travelling.—Illustrated Catalogues post-free.

J. W. ALLEN, Manufacturer of Officers' Barrack Furniture, and Military Outfitter, (see separate Catalogue, post-free,) 22 and 31 West Strand, London, W.C.

Bailey's Concentrated Fluid MAGNESIA, prepared with great care, and strongly recommended by the Faculty for removing BILE, ACIDITIES, and INDIGESTION, restoring APPETITE, preserving a moderate state of the bowels, and dissolving uric acid in GRAVEL and GOUT; also as an easy remedy for SEA SICKNESS, and for the febrile affection incident to childhood it is invaluable.—On the value of Magnesia as a remedial agent it is unnecessary to enlarge; but this Fluid Preparation is the most valued by the Profession, as it entirely avoids the possibility of those dangerous concretions usually resulting from the use of the article in powder.

Prepared by WILLIAM BAILEY and SON, Horseley fields Chemical Works, Wolverhampton. In bottles, 1s. and 2s. 6d. each, with Patent Glass Stoppers, particularly adapted for Exportation, as it will keep good for any length of time, and in every climate; also put up in Half-gallon and Gallon bottles, for the use of Hospitals, Dispensaries, and Compounding Prescriptions, at 5s. and 9s. each.

THE ACIDULATED SYRUP, in bottles 1s. each.

Sold by E. SLEE and Co., 46 Piccadilly, London,—Corner of the Albany,—and all respectable Medicine Vendors throughout the world.

MEDICAL ELECTRICITY WITHOUT SHOCK OR PAIN

PULVERMACHER'S PATENT

Galvanic Chain Bands sur- PASS in efficacy all remedies hitherto known for Neuralgia, Rheumatism, Paralysis, Head, Ear and Tooth Ache, Asthma, Bronchitis, Spasms, Gout, Nervous Affections, &c., &c., by infusing permanently and gently into the part affected that most wonderful natural agent Electricity. Their unparalleled success has established their celebrity throughout the civilised world, as may be seen by the striking proofs given in the book "PULVERMACHER'S IMPROVED MEDICO-GALVANIC SYSTEM.'

The Invention is adopted by the Académie de Médecine, Paris; the Royal College of Physicians, London; and by the Imperial Faculty of Vienna. It is also distinguished by the support of Sir C. Locock, Bart., Physician to her Majesty the Queen; Professor Oppolzer, Physician to the Emperor of Austria; by Dr Rayer, Physician to Napoleon III.; and others of celebrity; and was rewarded at the Great Exhibition of all Nations in 1851.

CHAIN BANDS, 5s., 10s. 6d., 15s., 18s., according to power, forwarded post free, to be had through all respectable Chemists, or of Messrs J. L. Pulvermacher and Co., 73 Oxford street, (adjoining Princess's Theatre,) London; where can also be obtained every description of ELECTRO-THERAPEUTIC APPARATUS and APPLIANCES of the most improved construction.

For Correct Family Arms, CREST, or PEDIGREE, send name and country, and 7s. 6d., to J. LOCK'S City Heraldic Office, No. 2 Old Jewry, E.C., London, and in a few days you will receive a neat drawing of your Arms, &c., in Heraldic Colours, to be engraved on Seal, Ring, or Family Plate. On y parle Français, Italien, Allemand, et Hollandais. Wedding orders executed

Important to the Medical PROFESSION.

GLOVER and Co., Wholesale Druggists, are supplying GENUINE DRUGS, CHEMICALS, and PHARMACEUTICAL PREPARATIONS of first-class quality at a very low figure.—Price Lists may be had on application.

CLINICAL LECTURES.

ON EXOPHTHALMIC GOITRE.

NEW FACTS TOWARDS A HISTORY OF THIS DISEASE.

Delivered at the Hôtel Dieu,

By M. TROUSSEAU.

(Continued from page 390.)

The woman in No. 34 Salle St Bernard is twenty-five years of age. She was born at Bagnolet, menstruated at thirteen, married unhappily, and is miserable. The nurse would have you believe that she is *cracked* in the head. She was delivered nine months ago; had then nothing resembling goitre, and was greatly astonished when told that her eyes were *droll:* they were, in fact, glistening and restless. Wishing to fasten her collar, she found that she was unable. The menses were next suppressed, the appetite became enormous, and the sight very short. At this moment, auscultation reveals an extremely soft bellows-sound, as in the chlorotic; the beatings of the heart are precipitous, the pulse varies between 110 and 130, and the patient's character is unequal and capricious. On applying the stethoscope to the goitre, there is perceived an expansive movement similar to that of an aneurismal tumour; and in the carotid artery you may perceive a purring tremor. This woman is emaciated, but not chlorotic. At first, martial preparations were given, and then all the symptoms became worse: iodine was next had recourse to, with cold applications, and leeches to the thighs and knees, under the influence of which menstruation was restored, and a very decided amelioration of the health became visible.

I have told you that in my practice I have met with nine cases of exophthalmic goitre. Furnished with these personal facts, and the cases recorded in the annals of science, I will endeavour to sketch for you an outline of this singular disease. Exophthalmic goitre is especially seen in women, and is certainly a neurosis. As the female sex is by far the most liable to nervous diseases, we may thus, perhaps, account for the predominance of this affection in women. I know but of two examples where it occurred in men, for the boy of 14½ years is but something intermediate between the two sexes. Certainly there are ages where the line of demarcation cannot be traced without difficulty. Stokes had under his care, in 1838, a man of lofty stature; and some other instances of this kind have been cited, but the majority is on the part of the women.

You are struck, when in the presence of such persons, with the singularity of their looks and the strange aspect of their eyes, the extraordinary lustre of which is equally observable in those who have black eyes and those that have blue. As the disease begins, the eyes enlarge, and become shining and prodident, even when there is not as yet any suspicion of goitre. At No. 27 Salle St Bernard, you may see a girl with exophthalmos, and who has, if you will excuse the expression, the eyes of a calf; but they are destitute of the lustre that characterises the eye in exophthalmic goitre, and are almost constantly shining, humid, and excessively restless.

In most patients, the organ of vision undergoes some modifications: such persons generally become myopic, but never strabismic. The woman seen by M. Labarraque, you remember, had *musca volitantes* and black points dancing before her eyes, and could no longer use her needle. Look at a person with exophthalmic goitre when asleep, and you see the eyelids half closed and but partially covering the sclerotica; yet in such patients ophthalmia is a rare occurrence. Such patients are not under conditions the same as persons affected with palsy of the seventh pair; for in this case the motive medium of the lid is lost, whilst in the morbid variety under consideration the patient may sometimes by an effort succeed in shutting the eyelids almost hermetically.

In palpitation of the heart, we have an unequivocal phenomenon. It is affirmed by Graves—that clinician so serious—that he saw a woman with exophthalmic goitre in whom the sounds of the heart could be heard at a distance of *four feet;* which is, in my opinion, one of the most extraordinary facts. Excepting on some rare occasions, I have never heard them beyond fifteen or twenty centimetres from the chest. Moreover, Graves, Stokes, Parry, Basedow, and several others, are convinced that in this case the affection of the heart is altogether nervous.

The goitre is equally the seat of similar beatings, and the lobes of the tumour are unequally swollen. The lobe usually most hypertrophied is the right. Stokes relates that, in one case, it was proposed to tie the common carotid, so much did the tumour by its pulsations and by its enormous size deceive the attendants as to be mistaken for aneurism. Fortunately, the error was discovered in time to prevent the operation.

When the stethoscope is applied over the apex or over the base of the heart, you hear vigorous beatings and a slight bellows-sound. If you place the instrument on the neck, you perceive a double *bruit de souffle*, resembling the sound noticed in aneurisms; but if on the goitre itself, you fail not to perceive an expansive bellowa-sound, quite distinct and defined. What is very remarkable, is the want of *solidarity* between the pulse at the wrist, in the arm, in the thigh and neck: when the pulsation of the carotid is strongly developed, the pulse at the wrist, in the arm and thigh, is nearly in its natural state. The epigastric pulse is sometimes more energetic; so that there is plainly a strange want of concordance in the vascular system.

In persons affected with exophthalmic goitre, in women especially, you remark nervous excitement, irascibility, and a degree of singularity altogether peculiar. M. Labarraque's patient, who, at his desire, came to me at the Hôtel-Dieu a few days ago, said that she could not bear the least noise or the slightest opposition. The woman at No. 34 Salle St Bernard has plainly now eccentric ways, such as did not before show themselves.

Exophthalmic goitre is not, therefore, a local affection, implicating only three points of the economy, but one that affects the whole system; and one of the phenomena that give the best evidence of a general disturbance, is the surprising hunger that has been remarked in so many cases. In Dr Gros' case, it is remarkable that the patient, when the disease was diminishing, gained in weight thirteen or fourteen kilogrammes in the space of twenty-eight or thirty days; an instance, surely, of extraordinary disturbance in the function of nutrition. Other patients, again, have shown a degree of emaciation that bore no relation to the quantity of food taken: but here a satisfactory explanation is possible; for, with profuse perspiration, intense diarrhœa, continued sleeplessness, and the frequent manifestation of nervous impatience, is it surprising that such patients should look wretched, and be pale and emaciated?

Lastly, you may sometimes witness the occurrence of some singular and inexplicable circumstances, as in the boy of 14½ years, who before his illness was exactly of a height the same as his mother, but in ten days he exceeded her by four centimetres. In the course of typhoid fever, but especially during convalescence therefrom, it is not unusual to see extraordinary increase of growth; but here, in a space of time so very limited, I own that this seems to me but little in conformity with all that we have hitherto seen. I shall speak, at our next conference, of the order in the evolution of the pathological triade, and will endeavour to prove, by numerous examples, that exophthalmic goitre must certainly have a place assigned it among the neuroses.

(To be continued.)

REMARKS ON THE CHOLERA WHICH RAGED IN TUSCANY IN 1855;

TOGETHER WITH AN ACCOUNT OF A NEW MODE OF TREATMENT.

By JOHN GASON, M.D.

In making the following remarks on the cholera which appeared at the Baths of Lucca in 1855, I shall state some ideas which an attentive observation of its progress has suggested to my mind. I purpose giving a hasty sketch of the non-infectious and non-contagious nature of that epidemic, the beneficial effects resulting from cleanliness and ventilation, and a novel mode of treatment which I used and found most efficacious.

The cholera at the Baths of Lucca was preceded for some weeks by looseness and an uneasy sensation of the bowels in numbers of the inhabitants. Its course was so rapid, that but little time was left for remedial agents, and it acquired the name of "Fulminante" from the Italians, who were so thunderstruck by its power, and even the native Physicians were so bewildered by its rapidity, that all attempts at cure were nearly abandoned, and the disease was almost left to take its course. From the month of February to October in that year, 25,950 persons died in Tuscany, out of a population of little more than 1,800,000: but it was somewhat remarkable that though there was a larger number of English and American visitors than usual at the Baths of Lucca during the time, but one case occurred amongst them, and that was under peculiar circumstances: this patient, however, recovered. Great confidence was entertained by the natives that this summer retreat would be spared; for in the previous year, when cholera visited Tuscany, numbers fled there from those places where the cholera prevailed, and still no case of it appeared. This cherished hope was, however, soon to be destroyed, as the cholera suddenly appeared, and the effect produced on the impressionable mind of the Italians was so great that they quickly succumbed to its power. The number of cases which occurred in the parts frequented by visitors (and which I shall alone refer to) was comparatively small; but in the immediate neighbourhood and the surrounding mountains, the aggregate number was great. The cases in the former amounted to 36, the deaths to 31, almost all in the stage of collapse, some few extending into the secondary stage, but these alike proved fatal. From four to eight hours was the usual duration of the attack. The symptoms so closely resembled those of Asiatic cholera, that I will not weary my readers by detailing them; only stating that the prostration was so great, that in the severest cases cramps were but seldom seen, and the discharges from the stomach and bowels exactly resembled bran mixed with water, the discharge being clearer than what is generally noticed in Asiatic cholera. The perspirations were copious and cold, and, with the exception of the dark-blue colour of the skin, the vomiting and purging, the general symptoms resembled those of persons dying from loss of blood. In many cases the bowels remained loaded, and lumbar worms were frequently discharged both from the mouth and anus. In one case which I treated, the alvine evacuations, on reaction, be-

came of a pinkish colour, resembling raspberry-juice mixed with water: later still the discharge from the stomach was green, and that from the bowels of a clayey colour. I shall now proceed to make a few observations on the nature of the disease as it came under my observation. The theories on its nature are so numerous and varied, that anything I may state may have been said before; but as I am not aware of this being the case, I shall give my ideas on the subject.

I have been led to look upon cholera in a different light from that in which it is generally considered, and that after weighing the objections which may be urged against my view of the subject. I believe that cholera is the result of hæmorrhage of the serum or white blood occurring under a peculiarly depressed state of the nervous system. The state of depression, I believe, is caused by loss of tone in the nerves supplying the mucous membrane and skin. The consequence of this hæmorrhage is the retardation of the red portion of the blood, which ceases to be propelled sufficiently quick to receive the necessary amount of purification from contact with the air: the result of this is the accumulation of a large quantity of venous blood, which poisons the system, and thus produces death by asphyxia. The combination of an unhealthy situation and various debilitating circumstances may tend to induce this loss of tone in the nervous system, and may predispose the individual to the epidemic which prevails at the time. The severity of the attack will, however, depend on the quantity of serum discharged, as well as on the nature of the epidemic, according as it may be typhoid in its nature or otherwise.

Having made these observations on the cholera which invaded Tuscany in 1855, together with some remarks on what I believe is its nature, I now pass on to some of the causes which appeared to favour its invasion and fatal progress. It was remarked, that during that summer there had been a great absence of wind, and that the air was very warm and moist, which depressed to a great degree the physical and nervous energy. This state of the atmosphere also favoured the decomposition of vegetable and animal matter in damp situations, and the gases so generated accumulated from the absence of wind to carry them off. Having formed a Sanitary Board at the Baths of Lucca, and having personally inspected the habitations of the poor, I am in a position to say that there was not a single case of cholera which did not occur in the midst of decomposing animal or vegetable matter. The police authorities lent every assistance to enforce the carrying out of our recommendations, and not a single case occurred afterwards in these parts where the cleansing was effected. Here I may mention a curious circumstance—that for many years previously to the invasion of the cholera, and particularly so in the preceding summer, there had been at the Baths of Lucca numerous cases of diarrhœa, some in a very severe form: since that time all tendency to the disease has ceased. How is this to be accounted for? Was the diarrhœa an accidental circumstance for at least five years previously, or did its exciting causes accumulate that year to such an extent that cholera was the result? The sanitary means adopted were the thorough cleaning of the houses both inside and outside, great attention being paid to the cleansing of the floors. Collections of all sorts were removed to a distance, and all the sewers in the neighbourhood were cleaned out. The bed-clothes were well washed, and great cleanliness of the person was enjoined. This physical exertion called off the mind from a state of apathy—which the natives appeared to be giving themselves up to—the poison which was polluting the atmosphere was got rid of, and with it the cholera ceased. I now pass on to the subject of contagion and infection in this disease. That all persons similarly circumstanced are liable to the disease, admits of no doubt; but why all persons in the same condition are not seized, is difficult of solution. In almost all the houses in which cholera occurred, there was but a single case; though there were instances to the contrary, and in one particularly, where a sewer communicated with a room in a basement story where the servants of the family used to assemble: in this house three of the servants died. In one of the cases which I attended, four of the children were constantly employed in rubbing their parent, who was ill of the disease; and though two of them were in the bed with her until she died, and notwithstanding that they washed all the clothes afterwards, still no other case occurred in the house. I could not detect any peculiar odour either from the body or the evacuations of the sufferers. Several cases of this description came under my observation, and have strengthened my conviction of its non-infectious and non-contagious nature. On my journey the same year from the Baths of Lucca to Rome, where it then was, I ascertained that the disease had in various cases passed over densely-crowded cities and towns, and attacked places situated on the summit (*a*) of lofty mountains which were at a distance from the high road, and not exposed to contagion or infection.

The treatment which I have been the first, I believe, to propose and adopt, which I tried in several cases in 1855, and which proved efficacious in all, I shall now mention. As soon as the serous evacuations commenced, I plugged the anus so as to prevent the further discharge of serum; at the same time I tightly swathed the bowels in flannel, and strictly enjoined that the patient should be kept in the horizontal posture. Some may object to the plugging of their anus, and in these cases I recommend a towel to be tightly rolled up and placed beneath the buttocks so as to compress the anus, the patient being warned at the same time of the absolute necessity of restraining every desire to go to stool, even though under the most urgent calls of nature. I found this treatment very efficacious in three or four cases. All liquids were strictly withheld, and gentle friction applied to the extremities; if vomiting or faintness continued, chloroform in small and frequently-repeated doses given on a lump of sugar proved of great service. Opiates appeared more injurious than beneficial, and seemed to aggravate the stage of reaction. The severity of the stage of reaction appears to depend on the severity and length of time of the stage of collapse. My object in writing this paper is to lay down a form of treatment which will be found, I believe, very efficacious in shortening and moderating the stage of collapse. I feel so sanguine of the result, that I only ask for a fair and unprejudiced trial to be made. The *rationale* of the treatment is very simple. We have a disease in which the system is being deprived of a large quantity of one of the vital principles of the blood: the object is to stop this, and what can be more natural than the means proposed? The bandage over the abdomen compresses the vessels, and by its pressure assists in preventing the discharge, at the same time that means are employed to cause reaction and produce absorption of what has been secreted. One more observation on the time of its employment. It should not be used during the stage of diarrhœa, when the bowels are discharging feculent matter, unless the symptoms appear urgent. Nor is there much use in trying it when the system is almost drained of its serum: it should be employed during the time that the serum is being discharged, and at as early a period as possible.

The power of testing the efficacy of this treatment was, I confess, limited; for having offered my Medical services to the authorities at the place, I was refused permission to practise on the natives, though it was well known that numbers were dying around to whom the native Medical men could not possibly attend: but in the cases which I did attend, I had recourse to the plugging of the anus, and in every case recovery took place. In one instance, the mother of a large family had for some hours frequent discharges of the "bran-water evacuations," which were continuing when I saw her. This discharge was immediately checked by the means which I have suggested. She was in a very listless and weak state; but reaction took place in the course of a short time, and she quickly recovered, though great debility existed for some weeks afterwards. This treatment I adopted within two or three days after the appearance of the cholera.

Rome, November 27, 1860.

(*a*) At Radicofani, a frontier town between Tuscany and the Roman States, situated about three hundred feet above the high road, the cholera carried off numbers at that time. The only source of infection alleged by the Italians was, that a cart of skins conveyed from Rome was opened at the Custom-house, and it was supposed that the poor may have caught it from these skins. This appears to me to be so far-fetched an idea, that it hardly deserves comment: for can it be reasonably supposed that the unloading of dried skins could have been such an object of attraction to the poor, as to induce them to remain close to these skins for any length of time, and that they, and not those engaged in the operation, should have carried the infection to this town? In all the places which I passed through, the mode by which the cholera was supposed to have been conveyed to the different localities was even more difficult of explanation.

CASE OF CONTAGIOUS SKIN AFFECTION,

RESULTING APPARENTLY FROM THE SCRATCH OF A KITTEN.

On the 21st of November, 1860, Mrs M. called to inform me that her little girl, æt. two years, was exceedingly ill from the effects of a kitten's scratch on the cheek, near the outer angle of the left eye. The accident happened about a week ago; the child had previously been in perfectly good health, and free from any eruption. The scratch for a day or two after it was inflicted, seemed likely to heal quickly; but the little girl picked off the scab which had formed, and a discharge appeared, purulent and thin at first, but it soon formed a prominent, irregular scab, under which the matter still continued to ooze for some time, and which at present is gradually dying away. The mother says that the matter sticks to the ends of the child's fingers, and being brought into contact by them with different parts of the skin, thus multiplies the number of sores.

Nov. 22.—I saw the little patient this morning, as she lay in her crib, almost as pale as a sheet. The face, ears, and neck were covered with red spots, pimples, pustules, scabs, and discharge. The ears were inflamed, and contained a good quantity of matter. The discharge, when brought into contact with any part of the surface of the body, although not previously abraded, caused in the first instance a small circular inflamed patch, in the centre of which a pimple could be distinctly seen, which gradually became converted into a pustule. The discharge soon appeared, followed by the crusts, under which it continued to ooze for some time. The sores, or rather eruptions, were plainly seen in their different stages of development. Before the parts got well, the discharge ceased, the crusts became drier and harder, and then gradually powdered away. Altogether it resembled a case of impetigo, so frequent in children teething; but the essential difference is that in this case the disease is clearly communicable by contact. The child is frequently in the habit of sitting on the lap of her sister, a healthy young girl of twelve years: wherever the child's fingers touch her, the disease appears on the spot, but the caustic application checks it. The little girl sleeps with her mother, whose neck she once touched with a finger, which Mrs M., in alarm, quickly pushed away; but the part soon felt irritable, and became slightly red. The nitrate of silver soon arrested its progress. Mrs M. says that the child was so feverish and restless, and in so much apparent pain, last night, that she did not expect her to live until the morning. Some sweet oil dropped into the ear seemed to relieve the pain. The oxide of zinc lotion was used.

Nov. 24.—The child appears to be in her usual good spirits; the discharge has ceased, and the scabs are disappearing. Her mother told me that she thought something burst in the little girl's ear, and she has been much better ever since.

Nov. 26th.—Much better; slept well last night, for the first time since she became ill. There is seldom any irritation during the day, but at night it is very troublesome. The back is affected, but the head scarcely at all, with the eruptions.

Nov. 27th.—The discharge continues from one or two scabs which the little patient had picked. The progress of the eruptions which break out on the mother and sister is invariably arrested by the nitrate of silver.

Dec. 5th.—The face is now quite clean, but there are a few scabs on the head. The lotion is still continued. The mother's forefinger and thumb have been much inflamed after dressing the child. She is much better now.

I may state that one of the little brothers, who is not allowed to touch the child, has not been

affected. It is a popular belief that the scratch of a cat is poisonous: this is obviously a mistaken notion. I attribute the little girl's rapid recovery in great measure to the application of the oxide of zinc lotion.

ANOTHER PHILO-CIRCULAR.

Pershore, Dec. 8th, 1860.

THE SPIRIT OF THE PERIODICALS.

Dr GOODFELLOW continues his Lectures

ON BRIGHT'S DISEASE

in the 'Medical Times and Gazette.' His special topic is *treatment*. He remarks that though bandaging is useful in certain cases, yet that it may produce disastrous and fatal consequences. When the anasarca is on the increase, a bandage ought never to be applied, the effusion being a temporary relief to the more important symptoms. He observes, also, that a spontaneous vesication, or even sloughing ulcer, is much less liable to spread than even an acupuncture with a lancet or grooved needle, which is often followed by erysipelas. He advises that the integument should be kept covered with flannel, to prevent chill; but he does not approve of hot-air or vapour baths in chronic cases. The Author then gives various suggestions on the treatment of scarlet fever, and the dropsy consequent to it.

The same journal contains a Report of a Lecture, by Dr RICHARDSON, on a Case of

CYANOSIS.

We extract the following remarks:

"Commenting on the physiological and pathological relationships of this case, we are first led to ask, What is the reason that the foramen ovale is left open in the manner depicted in these cases? Is it that there is congenital malformation? I think not. I look upon it as due to the deficient formation of that membrane, which, after birth, ascends from the lower margin of the foramen, and closes up, in the majority of cases, the foramen altogether. Why, in certain rare examples, this membrane should not form according to rule, it is not easy to explain at once; but I have given the subject considerable attention, and will narrate to you the matter of my researches. I would premise by stating, that the formation of the membrane is by no means a rapid process. In nine infants who died between the eighth and fourteenth days after birth, I found the foramen perfectly closed in no one instance, while in some the opening was not closed to a sixth of its extent: these children, nevertheless, were quite free from cyanosis. I followed out the subject further in inferior animals, especially in young pigs; and I deduce as the mean of those experiments, that, for the first three days of life, the foramen ovale remains patent, and that the closure is never completed under fourteen days. The last point that remains unclosed is a spot in the superior posterior border of the foramen. I show you a specimen where the membrane remains imperfect at this point, although the animal from which the heart was taken lived in perfect health for five weeks.

"We may accept, therefore, this view, that, for the first few days of life, the circulation is carried on, I may say normally, with a distinct opening between the right and left auricles.

"Is it strange that the two bloods do not intermix during this period? No; for if they did, no membrane would ever be formed in the presence of the intermingling currents; but the truth is, such intermixture is prevented by a simple hydrostatic law. You will remember that during fœtal life, owing to the fact that the lungs are impervious, a very limited quantity of blood passes by the pulmonary artery, and virtually none from the pulmonary veins into the left auricle; but the same current of blood before as after birth flows into the right auricle by the superior and the inferior cava: the result is, that as there is opposition to the current of blood through the right ventricle and pulmonary artery, while there is no opposition from the left auricle, the volume of the blood received by the right auricle is driven at once over from right auricle to left auricle, and then into left ventricle and aorta, when meeting with the little blood that flows from the pulmonary artery through the ductus arteriosus, it makes its way round the body to return to the placenta. But when the child is born, and the previously inactive lungs undergo expansion, then there is an immediate large demand of blood from the right ventricle and pulmonary artery for the pulmonic circulation, and with this there is an immediate supply of blood from the pulmonary veins to the left auricle.

"Thus there is established, on the one hand, a diversion of blood from the right auricle to the right ventricle, and, on the other hand, an opposition to the entrance of blood from the right auricle to the left auricle, by the fact of an independent current from the pulmonary veins being poured into the left auricle. In a word, a balance is established between the currents in the two auricles, and each current takes its course towards its respective ventricle. The two streams run side by side, but do not intermingle, and the membrane, which is ultimately to separate them, meets no opposition to its formation. The membrane itself is produced as an additional protection; for although in the first days of existence the risk is little of pulmonary obstruction, yet as time advances this risk increases; and were there no membrane there, any cause producing arrest in the pulmonary circulation would immediately lead to a diminished current of blood through the pulmonary veins, and to a transference of blood over from the right to the left auricle through the foramen.

"I once made a little instrument, of which I give you a drawing, in which the conditions of the fœtal circulation were imitated, by placing a diaphragm having a small hole in its centre through a glass tube. When fluid was pumped through the right side of this tube only, and the lower part of the right division was closed, a current of fluid passed freely through the hole in the diaphragm; but when the lower part of the right division was opened, and a free current of different coloured fluid was pumped through the upper part of the left tube, then the currents flowed independently of each other, and without admixture.

"If, then, we apply the above physical facts to the cause of cyanosis, I think that we are driven to the conclusion that the continuance of the patency of the foramen ovale is due in cyanosis to the persistence of the current of blood from the right to the left auricle; and that the continuance of this current is due, in its turn, to persistent obstruction in the lungs.

"The mode in which cyanosis terminates is a point of considerable interest: death ordinarily takes place, I believe, from pulmonary congestion, and unless there is some other lesion of the heart, such as valvular thickening, not from any other cause. Cyanotic patients are, by their peculiarity, almost exempt from inflammatory disorders; but they suffer readily from every depressing influence. Nevertheless, with the impure condition of blood to which they are subjected, with a portion of venous blood passing into the arterial capillaries, with deficient oxidation everywhere, and, *ergo*, with deficient warmth, they are supplied with nutritive force, with sensational force, and, as we have seen, with excellent mental faculties.

"In our patient, death took place from tubercle; but I would not attribute the tubercular deposit directly to the cyanosis. I would rather conceive that it arose from the imperfect hygienic conditions under which, from necessity, the patient was placed.

"Mark, however, how the cyanotic state modified the phthisical symptoms, took from them, if I may use such a term, all their activity, suppressed the hectic, prevented the local development of inflammatory products around the tubercular masses, and yet allowed the tubercular plasma to be deposited over a surface much larger than is met with, according to common experience, in ordinary cases of consumption.

"I fear I have omitted to comment on one diagnostic point in the case before us, which of all others should not be overlooked: I mean the physical diagnosis of the heart. In this child, notwithstanding the three openings in the septum, we learn that the heart-sounds were normal; and when no valvular lesion is present to produce an abnormal sound, this is, I believe, the case in all examples of cyanosis. It has been assumed, certainly, that there is something remarkable in this absence of abnormal sound in simple cyanosis; but if we accept the rational view that the normal cardiac sounds are produced purely by valvular tension, we can understand at once that the mere presence of an opening in the centre of the auricle can in no way modify the natural sounds when the valvular machinery is perfect."

Mr TURNER reports a Case of *Death from Hæmorrhage* after fracture of a rib without mark of external injury; and Dr HENRY OSBORN narrates some experiments and considerations on the *Detection of Lead in the Calcareous Deposits of Kettles and Boilers*.

The 'Lancet' contains the general conclusions of Dr BROWN SEQUARD on the diagnosis and treatment of *Paralysis*, which we will give in our next Number.

The 'Lancet' of the 8th. inst. contains the following remarks, by Dr PAVY,

ON DIABETES.

"Under the mode of procedure that used to be adopted, it certainly appeared satisfactorily proved, that whilst the blood in the arterial system was almost free from sugar, that in the right cavities of the heart—that, in fact, between the liver and the lungs—was highly charged with it. In obtaining these results, a specimen of blood was collected from an artery and examined. The life of the animal was then destroyed, and by an incision into the right auricle or ventricle their contents were procured. Now, unless certain precautions are observed, the necessity for which was not formerly known, such a method of experimenting must inevitably lead to a fallacious physiological conclusion. The knowledge required is of the state belonging to life, and this we fail to obtain unless we operate on blood, cardiac as well as arterial, that is collected before, or at the very instant of death.

"I was first led to observe this variation in the condition of the blood that takes place immediately after death, whilst conducting some experiments on the injection of blood through some artificially-inflated lungs, for the purpose of imitating what occurred during life. I had been in the habit at first of employing blood collected from the right side of the heart after death, but afterwards procured it from the living ventricle by a process, so to speak, of cardiac catheterism—an operation that is easily performed, without leading to any sensible injury to the animal. An instrument is used that is specially curved for the purpose. It is introduced into the right jugular vein, and passed down through the superior cava into the heart. I was astonished to find the blood thus collected present a totally different behaviour to what had hitherto been considered as belonging to it, from collecting and examining it after death. I had been accustomed to meet with a strong reaction of sugar as belonging to right ventricular blood; but in that withdrawn during life, I failed to discover more than a scarcely-appreciable indication of the presence of the saccharine principle.

"This observation, I must confess, did not at first receive from me the weight and attention it deserved. I was so strongly impressed with the notion that the gluco-genic doctrine was indisputably established, that I was for some time disposed to think there might be some fallacy in my experiment, rather than call in question the truth of our views. Seeking in vain for a source of fallacy, I afterwards found that what had been regarded as the natural state of the blood of the right side of the heart was not in reality such; that the blood collected, as had hitherto been done after death, did not behave like the blood removed during life; and, therefore, that an inference of the condition of the one from the examination of the other must be discarded as erroneous.

"I do not speak on this subject with any hesitation or doubt; as, to satisfy my own mind—to satisfy my own scruples in abandoning what I had so fully believed in, I was anxious that my experience should be sufficiently extensive to be

quite conclusive. I think I may say that it is now from an experience of nearly one hundred observations that my knowledge on this point is founded. When blood is collected from the right side of the heart, as in an ordinarily conducted examination after death, it yields a strong indication of the presence of sugar. In five quantitative analyses I found the proportion of sugar to vary from half a grain to nearly one grain per cent. in defibrinated blood. When collected, on the other hand, during life, under natural circumstances, the amount of sugar is certainly not more than is encountered in the arterial system. The reaction with the copper solution, which it must be remembered is an exceedingly sensitive test, is frequently so slight as to be liable to be overlooked altogether, unless special attention is given to it. I at first thought that the quantity of sugar would be too small to be susceptible of a quantitative determination. But I have since effected the examination. The greatest care was observed in the analysis, and the amount of sugar given me in the different specimens I have taken has varied from a proportion of $\frac{45}{1000}$ to $\frac{75}{1000}$ or $\frac{80}{1000}$ of a grain per cent. in the defibrinated blood.

"In conducting an examination of the blood belonging to life, it is necessary that the animal should be in a perfectly natural and tranquil state at the time of its removal. It is astonishing the immediate effect that a disturbance of the circulation produces. According to the behaviour of the animal, I can predicate, with confidence, the state of its blood as regards sugar. Should there be any struggling or embarrassment of the breathing, a considerable indication of the presence of sugar is certain to be met with. I consider that this unnatural flow of sugar into the circulation, under such circumstances, can be satisfactorily accounted for, and I shall refer to it further on when I am speaking of the liver.

"Under great disturbance of the circulation from embarrassment of the breathing, I had noticed so large an amount of sugar in the blood that I felt convinced it would be discoverable in the urine, if the condition were maintained a sufficient length of time. This is in reality the case, and even much more strikingly so than I had anticipated: for after muffling the muzzle of a dog, so that the supply of air is reduced, short of producing asphyxia, the urine in an hour's time is rendered very strongly saccharine.

"In comparing arterial blood with that of the right side of the heart removed during life, I have before now observed a stronger indication of sugar in the arterial than in the venous blood. This at first seems strange, but I believe it to be reasonably attributable to the effect of the difference in the operation performed for obtaining the blood. Catheterism of the ventricle is frequently effected without exciting the slightest disturbance; but in exposing the carotid—the artery usually selected for the removal of blood—a contrary result is the case, on account of the close connection existing between this vessel and the pneumogastric nerve. In picking up and isolating the former, the latter is always exposed to more or less violence or injury; and the pneumogastric does not bear irritation without causing strong muscular efforts at resistance on the part of the animal, which must occasion temporary congestion of the circulation and compression of the liver. Indeed, I have noticed that the blood is ordinarily found in a marked degree more saccharine when collected immediately after the exposure of the carotid, than when a short time, such as a quarter of an hour, is allowed to elapse after the isolation of this vessel, which may then be drawn out and its contents removed without producing any fresh disturbance of the animal's tranquillity.

"The administration of chloroform must be always avoided when a specimen of blood is required in a natural state as regards sugar. Chloroform not only reacts of itself with the copper solution, but through its influence on the circulation determines, as can be shown by experiment, to a more or less marked extent, an unnatural flow of sugar into the blood.

"The only point I know of in which Bernard's *results* and my own stand in opposition to each other is as to the blood collected from the right ventricle during life. In his 'Legons de Physiologie Expérimentale,' vol. i., p. 121, he records an experiment made before his class in which the blood removed from the right side of the living heart gave a neat reaction with the copper solution, whilst the blood of the carotid artery and jugular vein of the same animal gave no reaction at all. I do not doubt that we have here an accurate description of what was noticed, but it is in direct antagonism with the result I am confident in obtaining myself, and which I am frequently showing to others. If an extensive experience in this matter go for anything, Bernard's experiment is not to be taken as a representation of the natural condition. A fallacy may have arisen from the animal not having been in a tranquil state, and nothing was formerly known about the differences I have pointed out as observable in the blood under different conditions. Certain it is, according to my own experiments on the living animal, that sugar does not exist to a larger extent in the blood of the right side of the heart than what has hitherto been recognised as belonging to the blood of the arterial and the general venous systems; and that, should sugar appear to any amount in the right ventricular blood, it will also be found to a corresponding extent in that of the carotid artery and jugular vein.

"It is not absolutely necessary to resort to the operation of catheterism of the ventricle to obtain a specimen of blood presenting the natural character belonging to life. With the information now in our possession, the experiment may be so conducted as to display the physiological state after death, and I do not know that this is not the most preferable mode of operating, on account of the result being less liable to be influenced by accidental disturbing circumstances. Life is destroyed by pithing, and instantly afterwards the chest is as rapidly as possible opened, the heart seized, and a ligature firmly applied around its base. The blood is then collected from the right ventricle; and if the operation have been expeditiously effected, it will be found as free from saccharine impregnation as if catheterism of the heart had been performed under a tranquil state during life. The object is, to collect the contents of the ventricle before the blood has become contaminated with the sugar, which is produced in the liver with such astonishing rapidity after death. After the destruction of life by pithing, the circulation continues for a short time, whilst the process of respiration is instantly stopped. By this continuance of the circulation, the opportunity occurs for the impregnation of the blood with the sugar formed in the liver, as a post-mortem occurrence. Now, unless the steps of our experiment be quickly performed, the sugar will have reached the heart, and even have been carried through the lungs into the arterial system. There is nothing to be wondered at in this, seeing how quickly foreign agents introduced into the circulation have been found to be transported from one part of the system to another,—and seeing, as I shall hereafter point out, how quickly the saccharine principle is produced in the liver, as the result of the destruction of life.

"One of the principal arguments in support of the gluco-genic theory is, that, after the administration of animal food, the blood going to the liver is devoid of sugar, whilst that flowing from the organ is highly charged with it. I have touched upon one side of the question, and strenuously urged that the saccharine state of the blood which is found after death is not to be taken as a representation of its natural or physiological character. As to the blood on the other side of the liver, I have recently given it a careful comparative examination. In the experiments that I have made, and in which I scrupulously observed every precaution to obtain the specimens precisely in the condition that is natural to life, I could not perceive the slightest discoverable difference of behaviour between the blood of the portal vein and that of the right side of the heart. The portal blood gave the same trace of indication with the copper solution as I obtained with the cardiac contents. It was impossible, in fact, with the test reagent to recognise any distinction between the two.

"As far, then, as we learn from what has preceded, there is not, as a natural process of life, that flow of sugar into the circulation from the liver, for the purpose of destruction in the lungs, which the former mode of experimenting led physiologists to believe. After death, and under certain unnatural states during life, it is true, there is a large escape of sugar from the liver; but, as a normal condition, there is only a trace of sugar in the blood between the liver and lungs, and this trace is also met with on the other side of the lungs, in the blood returning from the system at large, and even in the blood on its passage to the liver. The blood, therefore—namely, that returning from the liver—which was formerly looked upon as affording evidence of the exercise of a gluco-genic function by this organ, has nothing special belonging to it. The same character is met with, as far as I can discover, to a precisely equal extent, in the blood of every part of the system.

"Quitting now the blood, I shall next direct my attention to the organ itself, which has for some years past been enjoying its reputed gluco-genic function."

The 'Lancet' of the 15th inst. contains an article, by Dr WILLIAM PIRRIE,

ON FAVUS,

We quote his conclusions:

"1. That favus is essentially characterised by the presence of a fungus, which is easily discovered by the microscope.

"2. That it is peculiar to the young, and confined to the poor and destitute.

"3. That it is most commonly met with on the scalp, but occasionally on other parts of the body.

"4. That the hair-follicles are only secondarily affected.

"5. That it is by no means a rare disease in Scotland, being exceedingly common in Edinburgh, and having been more so for several years past in Aberdeen than in Glasgow.

"6. That it is generally considered more common in Ireland than in England.

"7. That it is a blood disorder, and that the fungus is not the sole nor the original cause of the eruption.

"8. That many are insusceptible to it; and that it is feebly contagious, and very often arises independently of contagion.

"9. That the previous state of health has an important bearing on its outbreak.

"10. That it is intimately connected with the strumous diathesis.

"11. That want of cleanliness strongly predisposes to it.

"12. That, for its removal, general as well as local treatment is necessary."

The following Case of

ACUTE IDIOPATHIC GLOSSITIS

is reported by Dr GEOGHEGAN in the 'Dublin Medical Press:'

"M. K., a stout, healthy-looking man, æt. thirty-seven, of sanguine temperament, by occupation a cabman, admitted Oct. 9th, 1860. This patient is of regular habits, and not addicted to the use of tobacco. He cannot assign any definite cause for the present attack, except a late exposure to cold. Five days previously to his admission, Mr Woodroffe found him labouring under inflamed tonsils. Two days subsequently, enlargement of the tongue, accompanied by swelling of the soft parts beneath the chin, was visible, and has since steadily increased. Up to this period, the treatment had consisted in the employment of saline purgatives and antimony, but without mercury.

"On admission, the following conditions were observable: Tongue swollen to nearly twice its natural size, and filling the palatine arch; its edge infiltrated, translucent, and obtuse. The organ can be but very slightly protruded, when the raphe is observed to form a deep groove posteriorly. The back part of the left side of the dorsum is much more swollen than the right, and very sensitive on pressure; still greater tenderness is present at a corresponding point beneath the tongue where it joins the floor of the mouth. The crest of mucous membrane which runs forward along the latter towards the sublingual gland is vividly red, much swollen, infiltrated, and crested with opaque milky patches of fibrine of firm consistence and membranous aspect. There is a constant and copious flow of viscid, transparent, not frothy, fluid, (mucus?) from the mouth. Articulation and deglutition are much impaired. Breath heavy, but not fœtid. The gums present a narrow border of vivid red, and are slightly tumid. There is considerable swelling of the soft parts beneath the chin, with heat and obscure sense of deep fluctuation; skin somewhat hot; pulse 90, full. The fauces cannot be made visible. Symptomatic fever moderate.

"*Treatment.*—A narrow bistoury was introduced downwards and backwards beneath the tongue at the site of the sublingual tenderness above noted, and a

teaspoonful of greenish fœtid pus discharged. Six leeches were ordered to be applied beneath the tongue in the neighbourhood of the just-named opening, with frequent warm gargling of the mouth, and a poultice beneath the chin.

"Second day after admission.—Feels better; deglutition improved, and articulation somewhat so; much ptyalism, and breath has a *fœtid* and somewhat *stercoraceous* odour; tongue reduced in volume; swelling of left dorsum less, and tenderness there decidedly so. Sublingual mucous crest less prominent, and although the lymph of previous day had been then removed, is found again coated for one and a half inches by a layer of opaque white fibrine (under the microscope granular and not organised); the swelling beneath the chin more prominent and hot, with pain on deep pressure; pulse 96.

"Three only of the leeches took, but drew a large quantity of blood (estimated by the resident pupil from inspection of the vessel at *fourteen ounces*). Patient begs for a repetition of the leeches, owing to the relief experienced. Continue the poultice. Milk for food. Three more leeches beneath the tongue at left side.

"Third day.—Tongue generally less swollen and more moveable; swelling of left dorsum as before, but with scarcely any tenderness. The plastic matter on the sublingual crest, removed yesterday, has been reproduced. Fauces not yet visible, but anterior part of palate is seen to be healthy; edges of lower gums still redder than previously, and below the red margin is a milky looking film, interior of cheeks white and plastic; salivation still considerable, and breath fœtid; pulse 65; bowels confined; submental swelling still more prominent; an opening beneath the chin with the narrow bistoury evacuated a small quantity of healthy pus from a depth of at least three-quarters of an inch. Jal. et cal. 1 scrup., egg emulsion, with milk to be liberally supplied.

"Fourth day.—Still further improvement; tongue still diminishing in size; left dorsum continues swollen; fauces now visible. The sublingual fibrine has not been again secreted. State of gums and salivation as yesterday, but the fœtor has disappeared; submental abscess discharging a little healthy pus.

"Fifth day.—Salivation less, though still considerable; gums less tumid, but edge yet red; fulness of left dorsum continues; other conditions amended. Convalescent. Diet improved.

"Sixth day.—Salivation much less; much induration still beneath the chin.

"Seventh day.—Quite well.

"I availed myself of the present opportunity to investigate the condition of the salivary discharge, in reference to its normal ingredient, the sulphocyanide of potassium. Eight ounces of the fluid (the hematosine previously coagulated and removed) yielded by an appropriate procedure a spirituous extract, in which the presence of the sulphocyanide was at the best doubtful, whilst a *drachm* or less of *healthy saliva* gave marked indications of the salt. It thus appears that in other conditions beside *mercurial*, salivation of the sulphocyanide is absent, and hence that we cannot safely consider this negative character a distinctive criterion of the latter, as laid down by Dr Davidson. It seems to me, indeed, that it would be probably more correct to view the discharge, both in ptyalism and glossitis, and also in some secondary venereal and carcinomatous affections, as merely a mucous fluid, and not saliva, natural or otherwise."

The Author concludes with some remarks upon the case.

King's College Hospital.—The magnitude of the London Charities, their infinite variety, and the countless benefits which they confer on the sick and friendless poor of this vast Metropolis, have often excited the admiration of foreigners; but the most extraordinary part of their history is the fact that they have almost exclusively been founded by private benevolence, and, with few exceptions, are supported by the voluntary subscriptions of the charitable public. In a prominent place among these institutions stands King's College Hospital. The building, which covers an area of nearly an acre, and is in the Italian style, will contain accommodation for 200 patients, and will be replete with all the conveniences and appliances which, in this philanthropic age, are considered essential to the comfort and welfare of even the poorest patients. It is six stories in height, and, from the great extent of the building, the roof forms one of the conspicuous objects to be seen from the bridges, overtopping, as it does, both of the great theatres in the neighbourhood. When completed, it will have cost no less than 100,000*l.*, every shilling of which has been raised by voluntary subscriptions.

REVIEWS.

On Diphtheria. By Edward Headlam Greenhow, M.D.

From his official connection with the Privy Council, Dr Greenhow has had opportunities of studying Diphtheria on a large scale and under diversified conditions that cannot be enjoyed by other practitioners. He has also written after all the experience that was gained during the recent epidemic by practical men has been recorded: he has, therefore, the additional advantage of a comparison of their observations and suggestions to guide his judgment. We cannot be surprised, then, that our Author has produced a good book.

We have adverted to an epidemic, diphtheria; but, in reality, diphtheria cannot be regarded as exclusively epidemic. The conditions of its propagation are yet undefined; whether it be communicated by contagion or not is uncertain; and if due to atmospheric influences, these must be partial in their operation, as many cases may be observed in one locality, and few or none in another immediately adjacent. If local causes produce the disease or aggravate its intensity, these also remain in obscurity; and Dr Greenhow admits that he was unable to trace the occurrence of certain outbreaks of the affection to any deleterious influences arising from local pollution or domestic privation. There can be no doubt, moreover, that sporadic cases of the disease frequently occur. At this moment in the Metropolis there is prevalent a form of sore-throat, with a tendency in the buccal and tonsillary mucous membrane to secrete a pellicle of whitish exudation. These symptoms are accompanied with glandular swellings at the angle of the jaws,—in short, with the characteristic signs of diphtheria of a mild type. We believe this form of diphtheria to be not uncommon; though, on the other hand, it is pretty certain that numerous cases of scarlatina anginosa and maligna have been grouped under the new and fashionable phrase diphtheria.

Dr Greenhow commences his work with a chapter in which he gives a definition of the disease: we do not think, however, that either here or in other parts of his work he takes sufficient notice of one or two characteristic symptoms. We allude especially to the enormous swelling of the sub-maxillary glands, associated with infiltration of the cellular tissue of the neck, which prevails in some bad cases. He has very accurately described the condition of the inside of the throat, with the peculiar exudation; but he has nearly overlooked one symptom, at least, which in our experience has been one chief cause of the fatality of the disease. At page 203, indeed, he says, "More or less swelling of the glands at the angle of the lower jaw may be said to exist in every case. Sometimes it is very slight, at others very considerable;" and he adverts to a case where an incision into the tumour was made in his presence, and was followed by a "discharge of bloody sanies mixed with streaks of pus." This swelling deserves more important notice. We have seen several fatal cases of diphtheria, and we have formed the conviction that the mere mechanical pressure upon the nerves and bloodvessels of the immense swellings we have noticed has been sufficient to induce death. These indurations also present a mechanical impediment to deglutition, which has not been sufficiently considered. Dr Greenhow has properly described the sanious kind of fluid which occasionally issues when they are incised, or which may be discharged into the throat and cause instant suffocation, an instance of which we have seen. Pus it is not. These indurations feel and cut like a piece of brawn. We should like to have seen more attention bestowed upon this remarkable symptom in this work.

Towards the end of the work, Dr Greenhow describes the various sequelæ of diphtheria, and adverts to the nervous affections—paralysis particularly—that have been observed. The attention of practitioners was first called to the occurrence of paralysis after throat affections in connection with diphtheria; but latterly the same symptom has been noticed as a sequel of cynanche without the diphtheritic exudation. Does it follow, however, that the disease of the throat with false membrane, and that without, are two diseases different in essence? May they not be due to the same poison modified by circumstances? Whilst writing these lines, we have a young girl under treatment for facial paralysis on the left side, occurring immediately after an attack of sore-throat unattended with plastic exudation; yet we are inclined to think that the peculiar poison has been present in this case, as we have other cases where a thin greyish pellicle has been observed.

A considerable part of this work is occupied with a history of the various epidemics of diphtheria that have been recorded from the seventeenth century to the present time; so that a complete review of the disease is presented to the scientific reader.

Letts's Medical Diary for the Year 1861.

This useful Diary is so well known to the Profession, that our approbation of it is needless. It provides forms for registering daily visits, accouchements, vaccinations, and other engagements incidental to general practice.

The Cholera.—A letter received from Teheran at Constantinople on the 25th ultimo states that "the cholera which appeared at Yezd some little time back has reached Cashan, six or seven days from here. The Porte has, since the abolition of the frontier quarantine, determined on stationing a medical officer at Teheran in connection with the Intendance Sanitaire of Constantinople, as a kind of medical advanced post to watch the progress of any epidemic in this country, and has named Dr Binsenstein, late sanitary physician at Trebizond, to this important post. Dr Binsenstein was formerly sanitary physician at Van, Larissa, Heraclea, and the Dardanelles, and is a great acquisition to our medical world here." It thus appears that the Porte has commenced the institution of Medecins Sanitaires, as the French have done for the last ten or twelve years in all these quarters.—(Correspondent of the 'Lancet.')

Prize Subjects at the Paris Academie de Medecine for 1861, 1862.—The Academy Prize of 1000 francs for 1861—Disinfectants and their Therapeutical Application; for 1862—Determine by means of clinical facts, 1. What is the natural course of the various forms of pneumonia, considered with respect to the different physiological conditions of the patients? 2. What is the relative value of expectation in the treatment of these diseases? The Portal Prize of 1000 francs for 1861—Purulent Inflammation of the Lymphatic Vessels, and its Influence upon the Economy; for 1862—Vascular Obstructions of the Circulatory System of the Lungs, and the Practical Applications which may be deduced: that is to say, expound by means of positive observations the various species of sanguineous concretions which may obstruct the vessels of the pulmonary circulation, appreciating their causes, immediate effects, and ulterior consequences; investigate the mechanism of the cure of these morbid conditions, determine the signs which lead to their recognition, and indicate the treatment they call for. The Civrieux Prize of 2000 francs for 1861—Angina Pectoris; for 1862—Determine the Place of "Moral Medicine" in the treatment of Nervous Diseases. The Barbier Prizes of 4000 francs for 1861 and 1862, for Assured Means of Curing Diseases hitherto deemed Incurable; as, Hydrophobia, Cancer, Epilepsy, Scrofula, Typhus, Cholera, &c. Encouragements to be awarded to those who, without attaining the aim proposed by the prize, make some approach to it. The Itard Prize of 3000 francs for 1861 for the best work on Practical Medicine or Applied Therapeutics—such work having undergone the test of publication for at least two years. The Amussat Prize of 1000 francs for 1861 for the author of the work which, based on anatomy and experiments, shall have realised or prepared the way for the most important improvement in Surgical Therapeutics—such work not having already received any prize. The Orfila Prize of 4000 francs for 1862—Poisonous Fungi. The memoirs to be sent in by the 1st of March of the respective years.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B.—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, DECEMBER 26, 1860.

REFORM IN THE BARRACK-ROOM.

The spirit of improvement has, undoubtedly, taken possession of the higher Military Authorities, who, since the Crimean war, have become convinced of the paramount necessity of improving the moral and social condition of the soldier. His Royal Highness the Duke of Cambridge has been foremost in this laudable work; and, following his example, Sir Hugh Rose, the present Commander-in-Chief in India, has devoted himself with enthusiasm and energy to diversify the monotony of the barrack-room, and to meliorate the condition of military life. It is with extreme pleasure we advert to a General Order issued by him, in which he has required information as to the means already available at the several Indian Stations for the instruction of the troops. He also wishes to know the amount of accommodation for workshops and gymnastic exercises. This Order is so judicious and well-timed, that we quote it *in extenso*:

"Head-quarters, Calcutta, Oct. 6, 1860.

"The Commander-in-Chief wishes to place on a regular and permanent footing, and to render general, the means of recreation, instruction, and employment in useful trades, of the soldiers of the army.

"In this sense, His Excellency calls on officers commanding divisions to transmit to the Adjutant-General of the Army, reports, carefully drawn up, on the means in question which are actually in existence at the stations under their command, specifying their description and capability of improvement.

"For example: Whether there are barrack accommodations for schools; soldiers' reading and coffee rooms; workshops for instruction and practice in trades; gardens for growth of vegetables; gymnasia; single-stick practice; and cricket-grounds, skittle and ball alleys.

"The reports should also specify the capabilities which each station, and the country around it, afford for the practice of the various trades which in the soldier's hands may be the source of pastime and profit to themselves, and of essential use to troops in the field.

"Workshops, as a system, may be said to be unknown in this army. The Commander-in-Chief is most anxious that they should be introduced into it, and developed to the greatest possible extent; that not only soldiers, but their children also should learn trades.

"Sir Hugh Rose can speak from his own experience as to the advantage of soldiers knowing trades. It would have been a material advantage to the force under his orders in the late campaign, as well as to the service, if there had been soldiers in its ranks who worked in iron and wood; who could have repaired damaged rifles, saddlery tents, &c., made shoes and summer clothing. There was plenty of material, wood, iron, khakee cloth, leather, &c., but, unfortunately, next to no workmen.

"General Officers are invited to offer any suggestions which may occur to them, and to elicit information from officers commanding regiments on the important subject of this General Order, which has for its object the useful occupation of the soldier's long leisure during an Indian hot season, as well as his comfort and welfare, whilst in the service, and after he has left it.

"Useful occupation must be the means of raising the moral condition of the soldier; it causes habits of order and industry to take the place of idleness and intemperance, which enervate the best health, the noblest energies, the ablest intellects.

"Useful occupation has further advantages. It enables a soldier to gain a competency whilst in the service, and a livelihood when he returns to his home. It enables him to bring up well his family, to assist aged parents, and to settle down into a good and useful member of the State.

"By order of His Excellency the Commander-in-Chief.

"W. MAYNEW, Lieut.-Colonel,
"Adjutant General of the Army."

This admirable document recommends itself to the common sense of every reader. The bane of soldiers in time of peace is idleness; and as an idle man cannot exist long without a stimulus of some kind, the soldier, in default of other resources, resorts to the canteen, and tries to cheer the wearisome monotony of his routine existence with a debauch. The fearful oppressiveness of this listlessness, added to the unvarying regularity of the duties and the repulsiveness of the drill, is sufficiently exemplified by the desertions, suicides, and other crimes for which soldiers are unhappily too notorious. Variety of occupation is one of the chief solaces of life, and is, undoubtedly, one of the most efficacious means of maintaining the spring of the faculties unimpaired.

During the Crimean war, the helplessnes of the British soldier was a subject of common remark. Although perishing from the rigour of the elements, and from lack of food, it was found that he did not possess sufficient mechanical knowledge to enable him "to turn his hand" to any work necessary to improve his condition. He was unable to help himself, and required that others should build for him, dig for him, cook for him, and, in fact, do everything needful to his precarious existence. Should the objects at which Sir Hugh Rose aims in the foregoing Orders be fully realised, the British soldier will be, ten years hence, a far different man from what he now is, and the service, deprived of its irksomeness, will cease to be regarded with aversion by the better class of artizans. The health of the Army will, no doubt, be much enhanced by these arrangements, and, in India especially, the sick and mortality lists will be considerably reduced.

We hope that in any further inquiries which the Commander-in-Chief may conduct into these matters, he will enlist the co-operation of the Medical Officers, whose special duties and opportunities qualify them to give sound and reliable advice, and whose opinions will command an influence among the public that does not generally follow the reports of Commanding Officers. We regard these "Orders" with peculiar interest, and trust that they may be effectually carried out.

SUMMARY OF THE WEEK.

CHOLERA IN THE EAST OF LONDON.

An alarm of cholera has been raised in West Ham, the particular district of the Metropolis where cases of cholera are usually first noticed when an epidemic looms over this great city. A Committee of Medical Officers has inquired into the facts, and reported upon those cases in which death occurred within a few hours—varying from twelve to twenty-four—from the commencement of the attack. In neither case was the purging of the rice-water character; and there were no cramps, and no suppression of urine. On the other hand, there was bilious vomiting and purging, with delirium and coma;—in short, the cases were not cholera: then what were they? Were they due to some specific poison? So it appears to us, and we hope that an attempt will be made to discover the cause.

UNWHOLESOME MEAT.

The City Authorities are vigorously carrying out their powers for the seizure of unwholesome meat in Newgate Market. The vast quantities of bad meat that are sent to this Market for sale are almost incredible, and it requires the utmost vigilance to prevent its getting into consumption. Unfortunately, there is no Act of Parliament so stringent that it cannot be evaded by a subtle Counsel, and it appears that it is very difficult to prove that in any given case the meat was consigned to the Market by the sender with the intention of its being exposed for sale as human food; so that, although the meat can be secured and destroyed, the culprit may escape the fine; and unless a fine can be imposed, the practice cannot be effectually restrained. Public opinion should be strongly expressed on this point, in order that the hands of the Medical Officers of Health may be strengthened in the discharge of their duty.

DUIGAN *v.* WILKINSON.

A case has been tried at Gainsborough of some interest to Surgeons. The defendant was the father of a boy, who was a servant in a private family, and who sustained a compound fracture of the thigh. Dr Duigan, who was the Surgeon in attendance, sued the defendant for the sum of 10*l.* 10s., the amount of his bill. The defendant pleaded malpraxis. The limb was at first put up in the straight position, but nineteen days afterwards it was considered necessary, owing to the excessive discharge, and in order to enable the surgeon conveniently to dress the wound, to put it on a double-inclined plane. Thus matters re-

mained for another fortnight, when union was found to have taken place, and a mill-board splint was applied to enable the boy to get about on crutches,—an opening being left for the escape of the discharge, which was now trifling. On Dr Duigan's calling nine days afterwards, it appears that the boy had not been got out of bed; the Doctor was cross, and did not call again, but four days subsequently sent Mr Spencer to see the case; and three or four days afterwards that gentleman reported that the father had cut away a portion of the splints and bandages, and that the knee was swollen from the unevenness of the pressure. The father, in his evidence, said that after the leg was first set up, the boy cried terribly, and that the limb was not interfered with for three weeks, when, the bandages being removed, a basinful of matter gushed from the wound; and at a subsequent period he cut the bandages, to enable the blood to circulate in the limb.

Dr Mackinder, Mr Fairchild, and Mr Cook, of Gainsborough, were called on behalf of Dr Duigan, and deposed to the propriety of his practice in every particular. It seems, however, that after Dr Duigan had relinquished the case, a man called Adams, a bone-setter, saw the boy, but did not interfere further than to administer decoctions. Then, Mr Drust, a Student of the Middlesex Hospital, and Mr Skelton, a Student of St Bartholomew's, also saw the case, but did not interfere. Mr Drust had been formerly an assistant in a grammar-school; and Mr Skelton admitted that he was a compounder of vegetable pills and medicines. These witnesses deposed that they found the limb considerably shortened, with an abscess in the lower part of the leg. Mr Skelton now called in Mr Skey of St Bartholomew's; and with the appearance o this gentleman on the scene, the drama acquired fresh interest. Mr Skey stated that he found the limb shortened to the extent of from three to four inches, the lower part lying at an angle with the upper part of 40 degrees, with a large collection of matter around the bone. The ends of the bones being united, he deemed it necessary to break the bone again, which he did; he then applied pulleys for three-quarters of an hour, and reduced the shortening to within 1¼ inch or 1½ inch of the original length.

A question arose, whether, in the interval between Dr Duigan's leaving the case and Mr Skey's seeing it, the bones might have separated and reunited. Mr Skey thought there was not sufficient time for this process. We cannot enter into further detail: it is, however, with satisfaction that we find the Judge deciding in favour of the plaintiff for the full amount charged. Had Dr Duigan continued his attendance until the entire recovery, the unpleasant incidents that subsequently occurred might have been averted. It was not quite right to desert the case from pique, because a certain order had not been complied with. However, the witnesses do not impeach his skill up to the time of his last attendance.

SPECIAL HOSPITALS.

Sir Benjamin Brodie, our readers will remember, when he wrote his Protest against Special Hospitals, made an exception in favour of Ophthalmic Institutions. We now find that Sir Charles Locock, also a protester, has publicly excepted from condemnation Lying-in Charities. We have no doubt that a considerable number of the protesters have also their pet Institutions. When will the reign of humbug as patronised by our contemporary the 'Lancet' come to an end? The following is the letter written by Sir Charles Locock to his friend Mr Ikin of Leeds:

"Holmewood, Tunbridge Wells,
"August 14, 1860.

"My dear Sir,—Having left London some time since, your letter has followed me here. Mr Erichsen sent me the Protest against Special Hospitals about a month ago, accompanied by Sir B. Brodie's letter already in print. I signed the Protest, but at the same time sent a letter to Mr Erichsen, saying that I did so only because I considered that there had been, of late, a great abuse in starting and maintaining Special Hospitals to a most unwarrantable excess; but that the same exceptions which Sir Benjamin Brodie had made in regard to Ophthalmic Hospitals, I still more emphatically made in respect to Lying-in Hospitals, and those for the Diseases of Women and Children. They did not choose, it appears, to print and circulate my letter of exceptions, as I suppose they thought many others would also have their own pet exceptions.

"Yours very faithfully,
"J. I. Ikin, Esq." "C. Locock.

The Adulteration of Bread with Alum.—Five bakers, named Ratcliffe, Scholl, Verge, Lambert, and Brett, were summoned to the Wandsworth Police Court, on the 15th instant, for unlawfully using alum in the manufacture of bread. The proportions employed varied from 27 to 80 grains in a quartern loaf. Mr Ingham (magistrate) inflicted penalties of 5*l.* and 10*l.* each, and costs ranging from 3*l.* 5*s.* to 4*l.* 8*s.* The informations were laid by Mr John Dart, the inspector of weights and measures for the district, under the 3rd of George IV., c. 106, in the following terms:—"That within forty-eight hours before the making of the complaint, and within ten miles of the Royal Exchange, being a person making bread for sale, he did, in the making of bread for sale within such limits, use a certain mixture and ingredient, to wit, alum, in the making of such bread, other and except as mentioned in the statute in the case made and provided." The analyst was Dr Normandy.

Funeral of the late Sir Henry Marsh.—The funeral of the late Sir Henry Marsh took place last week, when his remains were interred in Mount Jerome Cemetery. The funeral was attended more largely than any which has taken place in Dublin for years past. There were upwards of 150 carriages in the procession, and almost all the gentlemen connected with the Profession of which the deceased baronet was so distinguished a member attended the funeral. A number of the tenants from the family estate at Kilkenny came up to Dublin for the purpose of attending the burial. The mace of the College of Physicians was carried behind the mourning carriage. It was the intention of the students belonging to the Medical Schools in Dublin to have walked in procession behind the hearse, but the inclemency of the weather prevented this arrangement being carried into effect. A great number of students, however, were in attendance. Since Saturday the principal Schools of Medicine in Dublin have been closed in respect to the memory of the late baronet, and the meeting of the Pathological Society, which was to have been held on Saturday, was postponed in consequence of the melancholy event.

GENERAL CORRESPONDENCE.

POOR-LAW MEDICAL OFFICERS AND THEIR GRIEVANCES.

To the Editor of the Medical Circular.

Sir,—Every Poor-law Medical Officer, except Mr Griffin, must be perfectly aware that any measure proposed for their relief would meet the determined opposition of the Poor-law Board, provided it contained a clause so unreasonable as that relating to a Medical Secretary to be appointd by the Medical Officers themselves. Mr Estcourt, in his interview with the Poor-law Medical Officers, clearly pointed out to them the evil tendency of such an appointment; yet, singularly enough, to this clause alone, in his many draft bills, has Mr Griffin adhered. It would almost give the impression to those who are not aware of the thorough disinterestedness of Mr Griffin, that he had in his mind some person ready for the office.

I fear the stoppage of pecuniary supplies will prevent any further "*Draft of an Act, &c.,*" being circulated for the present; but if the proposition of Dr Ashburne, of Pendleton, that magistrates at Quarter Sessions should fix the scale of payment in their respective counties, was brought before Parliament, it would probably be received with assent. They have already the control of one class of Medical Officers—viz., Surgeons to County Gaols; and we know they are amongst the best-paid servants of the public.

I am, &c., C. H. N.

December 15, 1860.

THE PROPOSED JUBILEE TESTIMONIAL TO EDMUND BELFOUR, ESQ.

To the Editor of the Medical Circular.

Sir,—As thoughts upon the same subject often arise at the same time in minds far apart, and letters on the same points cross in their transit, so I shall probably find that *your* views have met mine far more than half-way on the road, in the shape of further editorial remarks in addition to those which early appeared in the Circular (about a month since) in reference to the above subject, by *which* my attention was first drawn to it.

I have been waiting, like many others, for the appearance of an advertisement naming the channel through which I could add my guinea to the subscription which, I doubt not, has already been set on foot, to give the Profession at large the opportunity of marking their sense of the great and meritorious services—far beyond mere official duties—which have been rendered by Mr Belfour during the very long and unprecedented period he has performed so well the somewhat arduous duties of Secretary to the College of Surgeons.

As a principle—for I look to merit, not the man—I am desirous to bear my individual testimony to that which it is imperative upon us to uphold, as a moral which we should set forth to those coming after us, for it is by marking our appreciation of worth that we stimulate others to excellence. I cannot forbear remarking, that associated with the name of Belfour is a *double stay.* Not only has his stay in office been a long stay—half a century!—but his has been a very valuable stay also to the Council, to whom, as has been observed by a writer in another print, "there is a good margin left for adding their own guineas to those they have given out of the College Funds," in due acknowledgment thereof. In every way, therefore, has Mr Belfour been an exception to ordinary rule.

While his long career of office has been signalised by a devotion which money could not purchase, and none but innate principle secure, he, by his great vigilance and exertion, has done much to uphold the best interests of the Members of the College, and to promote the respectability of the Profession.

In conclusion, let it not be supposed that in pointing to merit I desire to plead for it. My province extends not beyond the duty attaching to all—the acknowledgment of it—for the reasons I have stated. I am, Sir,

Your constant reader,

December 14, 1860. Rusticus.

[We recommend the subject of this letter to the consideration of our readers.—Ed. Med. Circ.]

HOSPITAL REPORTS.

UNIVERSITY COLLEGE HOSPITAL, Dec. 12.

Case of Hernia, Wutzer's Operation.—Mr Erichsen.

Mr Erichsen took the opportunity to alludo to the surgical means in practice for the cure of hernia.. He said, those at present adopted had become limited to two several measures which met with approval and success. He described the means employed in the performance of Wützer's operation. The integuments of the scrotum were forcibly invaginated by the introduction of a wooden, metal, or bone plug into the inguinal canal. This plug admitted a curved needle being passed through it in a groove which pierced the integuments at the inguinal ring. The extremity of this needle, after being passed through the plug, was secured by a clamp button on the surface externally, having a screw over to secure its point. The proximal extremity of the plug was also secured by another clamp with screws. The object of this proceeding was to make the integument of the scrotum a plug to fill up the inguinal canal, the wooden plug to be retained for a sufficient period for that purpose. Thus a slight inflammatory action intervenes sufficient to induce adhesion of the parts in the canal and ring, and by that means to permanently plug up the canal against the passage or return of the hernia. The merit of this operation was its simplicity, and its entire freedom from all danger. If it did not succeed, the state of things was only in the condition they were found before the operation. No danger occurs, no cutting process being adopted endangering the occurrence of erysipelas or other casualty, and a fatal result has never, Mr Erichsen believes, happened upon its performance in this country. It is only to be recommended to be adopted in small and recent hernia. The other operation—Wood's operation, so called from that gentleman having introduced its practice—is also done by invagination. In his procedure, invagination of the fascia and tissues is practised, and a cutting operation performed. An incision is made, and the fascia separated for some distance with a tenotomy knife at the scrotum. The dissected and denuded fascia are then invaginated and passed up the inguinal canal to the pillars of the ring. A needle armed with ligature passed through the canal thus invaginated to the external pillar is carried through the integuments, piercing the conjoined tendon at Poupart's ligament. Another ligature is similarly passed through the integuments at the internal pillar; so that when these two ligatures are tied together, Mr Erichsen said, they included the two pillars of the ring. This process sets up an inflammatory action, the canal becomes occluded by adhesion of the parts, and curé of hernia is induced. This operation, Mr Erichsen said, was suitable for old and large herniæ, and, he believed, had been attended with success, but he had not performed it. He had been informed, and he believed his information was correct, that under the hands of a very eminent surgeon a fatal result had occurred from this operation. But such accidents would happen under any operator and from any operation, however trivial — erysipelas or other accidents occurring. The patient to be operated upon was a young man about nineteen years of age. Mr Erichsen did not think the occasion of so simple a procedure justified incurring the small hazard attending the administration of chloroform: he consequently dispensed with its use, although the patient was desirous to have it administered. The hernia was small and of recent date.

Mr Erichsen alluded to the operation performed at this hospital a few weeks since by Mr Henry Thompson. It was a new operation, as we described at the time, the fascia being denuded by an instrument Mr Thompson had invented for the purpose.

Rodent Ulcer.

The patient upon whom about a month since Mr Erichsen applied nitric acid to the orbit of the right eye, which had become invaded by rodent ulcer, to destroy by caustic some remaining disease, was brought into the operating theatre to have performed some plastic surgery upon the orbit. On examining the orbit, which showed a very improved appearance, and healthy granulations filling up and contracting its circumference, Mr Erichsen discovered at the bottom some yellow spots which denoted a diseased character. He thought it prudent to defer the operation of a plastic nature for the present. In place, he applied the actual cautery to these suspicious points. He remarked that it was desirable, and almost necessary, to obtain by plastic means an integumental covering for the hollow chasm in the orbit produced by the destruction of the eye. If not, particles of dust and dirt and extraneous matters would be always collecting in the orbit, inducing irritation and renewal of disease. He said, ample opportunity would be given for this by the surrounding integuments. Moreover, it was desirable to attain as much contraction of the circumference of the soft parts of the orbit of this destroyed eye as possible, by healthful and firm granulations, in order to close this chasm by bringing it as nearly to a level with the surface as possible.

GUY'S HOSPITAL.

Dec. 11th. — Removal of Tumour from Breast. — Mr Birkett. Amputation of Conical Stump.—Mr Hilton.

Tumour of Breast.

The history of this case was curious. The patient, a female about forty-five years of age, had been operated upon in Guy's, by Mr Cooper Forster, about seven years since, for adenocele in the right breast. It had assumed a peculiar character. The tumour was seated upon the superior aspect of the breast, and had arrived at a large growth, the size of two closed fists. The tension of the skin and tissues had become so great, that the tumour ulcerated, and presented the appearance of an immense cauliflower. She had consulted several Cancer Doctors, who were frightened at the appearance of the ulcer, and would have nothing to do with the case. In consultation, it was decided to be adenocele, and to be free from any malignant character. Mr Forster on that occasion removed the tumour. The patient quickly recovered, and was recommended to leave the hospital for the country to restore her health, which had become greatly reduced by discharge from the ulcer and irritation thus induced. Mr Birkett said, that a fortnight after her discharge he carefully examined the breast, and found it perfectly healed and in a satisfactory state. About three years after, a small tumour became again perceptible, which gradually increased to its present size, which was not large. Mr Birkett suspected it to be a cyst containing yellowish matter, and to be of a perfectly innocent character. He removed the whole mammary gland. Upon cutting into the growth, it presented a glairy fibro-plastic structure. The woman appeared to be in robust health, and in good condition to undergo the operation.

Conical Stump.

Mr Hilton stated that he removed the right leg of this patient, a boy about eighteen years of age, seven years ago, by amputation at its upper third. He believed the stump at the time was a very good one. Outgrowth had occurred of the tibia, the fibula not having participated in this excessive development, and was not to be discovered for three inches above the stump or extremity of the tibia. This was a state of things rather unusual, excessive instead of diminished development having occurred. Mr Hilton made incisions in the old cicatrices, dissected back the integuments, and removed, with Butcher's saw, about two inches of the bone of the tibia. He brought the flaps together with hare-lip pins and ligatures, and applied strapping.

KING'S COLLEGE HOSPITAL.

Dec. 15th.—Staphyloraphy.—Mr Fergusson.

Staphyloraphy.

This patient, a young girl of ten years of age, was submitted, although so young, to the operation for cure of cleft palate. Her mother had consented and she was desirous herself to have the operation performed; and the presence of her usual medical attendant gave confidence and sanction to this procedure. The difficulties were necessarily great in consequence of her youth, but were completely overcome by the great patience practised by Mr Fergusson during the operation, which was of a trying and tedious character. The opposition of the girl and her resistance at every step were painful to witness, reminding one of the olden time when chloroform was not known. This demonstration was relieved by admiration induced at the triumph obtained over these difficulties by the operator. The patient was a vigorous, well-grown girl, not easily constrained by the attendants in the absence of the influence of chloroform. Mr Fergusson made a few remarks. He said, the performance of this operation under the circumstances was exceedingly trying to the temper of the surgeon. He referred to the case operated upon last week for cleft palate: the self-possession and moral fortitude of the patient on that occasion aided the proceeding, which was satisfactorily concluded, notwithstanding it was a very unfavourable day, from its darkness, for the purpose. Mr Fergusson remarked that many patients came to the operating-room fully prepared and resolved for the occasion. The moment the first incision was made, all this fortitude fled, and the succeeding stages were painful conflicts between the patient and operator; the one in the performance of his anxious and responsible duty, pertinaciously resisted by the other, unless under the influence of chloroform. He said this much to explain what he meant by "trying the temper of the surgeon." The surgeon's temper ought never to be so implicated. Thanks to the valuable assistance of chloroform, this is not the case at present. Staphyloraphy is almost the only operation of surgery in which you cannot resort to the influence of chloroform. In the performance of this operation for cleft palate, Mr Fergusson said, you want the consent of the patient for the accomplishment of your object at every stage. You must have his free will, and the patient must be possessed of complete volition. In short, *you* operate, and by his willingness *he* assists. You otherwise cannot make him open his mouth by any mode, not even by force. You then have to obtain the proper position by which light may be admitted and reflected at a suitable angle for your purpose. Your own manipulations, Mr Fergusson said, also intervene and intercept vision of the parts to be operated upon. These are trials of patience and temper, since *anæsthetics* are impossible. In enlarged tonsils, where you have to make only one section, they (chloroform, for instance) can be resorted to. The section made, the whole process is concluded. In this case we have had resistance from beginning to end. At best, this operation seems a boggling, stitching, and cobbling piece of business. Fortunately, this was a very favourable case, the soft parts being only cleft, the hard palate not being implicated. The operation was consequently simple and comparatively facile. After the usual and necessary division of the *levatores palati* muscle, and paring edges of the fissure with a straight blunt-pointed bistoury, thus removing only the mucous membrane, the anterior and posterior pillars of the fauces, if necessary, are divided with blunt-pointed scissors about a fourth of an inch. The operation is concluded by insertion of sutures with the *retroverted* hooked needle which we described last week in reporting a similar operation. Notwithstanding the continuous resistance of the patient throughout, the edges were nicely and accurately approximated, giving promise of a good and satisfactory cure.

WESTMINSTER HOSPITAL.

Dec. 18th.—Extensive Nævus over the Orbit, Face, and Frontal Scalp; Partial Ligature of.—Mr Holt. Necrosis of Lower Extremity of Ulna.—Mr Brooke.

Nævus.

This patient, a boy about eight years of age, had an extensive growth of erectile subcutaneous tissue over the nose, face, orbit of right eye, and eyelids of the same, extending also over the forehead and head of the same side. It consisted of small, dense, nodulated tumours. These nodules on the head were of a dull, swarthy aspect, being sulcated in elevated convolutions, which gave them the appearance of a curled wig placed on the head. Mr Holt had made two or three partial applications of ligature to one of these (the largest) tumours, situated between the nose and orbit, and ulceration of the integuments existed. He applied the ligature again to-day to the same tumour. A stroog silk ligature was very tightly twisted twice round the base of the tumour under pins which had been first introduced. When this had sloughed away, Mr Holt proposed to apply the chloride of zinc as a caustic to destroy the remaining tissues. He also proposed to attack the other portions of this extensive erectile growth with ligature in

sectional parts; caustic being also afterwards resorted to, to effect their destruction.

NECROSIS OF ULNA.

This patient, a man about forty-five years of age, had for some time suffered from necrosis and caries of the lower extremity of the ulna. The carpal joint did not appear to be implicated, and the disease was apparently limited to the ulna. Mr Brooke made an incision longitudinally through a sinus at the posterior aspect of the arm, and recovered considerable portions and fragments of necrosed and carious bone. He then introduced lint into the wound, and water-dressings were applied.

ST GEORGE'S HOSPITAL.

DEC. 20TH.—REMOVAL OF FATTY TUMOUR FROM SHOULDER—MR JOHNSON.

This patient, a young woman of about twenty years of age, had a fatty tumour of recent growth on the external aspect of the superior part of the arm, below the shoulder. Mr Johnson, on removing it, dissected away several nodulated cysts containing fatty matter.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DEC. 5TH, 1860.

DR TYLER SMITH, V.P., IN THE CHAIR.

This being the last meeting of the second session, the following gentlemen were appointed to audit the accounts for the year 1860:—Dr Braxton Hicks and Mr J. T. Mitchell, F.R.C.S.

Dr TANNER exhibited a

LARGE COLLOID TUMOUR OF THE OVARY.

This tumour, which weighed upwards of 8 lb avoirdupois, was removed from a patient of Dr Robert Fowler. The woman was thirty years of age, and was doing very well, eleven days having elapsed since the time Dr Tanner operated. The operation was performed as a last resource to save life, since the patient was not only suffering from the tumour, but also from ascites produced by it. Five days before the performance of ovariotomy, tapping was resorted to, and fourteen pints of ascitic fluid withdrawn; yet at the operation it was found that about five pints of fluid had been again secreted. With regard to the operation itself, there was one point deserving of mention, —namely, that after applying ligatures to the pedicle, the tumour, instead of the pedicle, was cut through, and a portion about the size of a small hand left attached, which was retained outside the abdomen. By this proceeding the use of the clamp was rendered unnecessary, while all risk of hæmorrhage was avoided. The latter point was of no little importance, since bleeding from the pedicle had been the cause of death in no less than 16 per cent. of the fatal cases. The edges of the wound were carefully brought together with twine sutures; these latter not being passed through the peritoneum.

In reply to a question from Dr Tanner,

Mr SPENCER WELLS said he had attached the greatest possible importance to the practice of passing the metallic sutures or hare-lip pins through the peritoneal edges of the wound. He had been led to originate this practice by observing the inner aspect of the wound in the first fatal case of ovariotomy which had occurred in his practice. The sutures had been passed through integuments and muscle, but not through the peritoneum; and the consequence was that a raw surface of considerable breadth was only partially protected from the general peritoneal cavity by a portion of intestine, which was already adhering to it, although the patient died the day after the operation. Had she lived longer, there could be no doubt that pus or other secretions from the wounded surface would have been poured into the cavity of the peritoneum. Struck by this observation, he (Mr Wells) made a number of experiments, in concert with Dr Richardson (who narcotized the animals by puff-ball smoke or chloroform), upon guinea-pigs, rabbits, and dogs, opening the peritoneum and closing the wound in some cases by sutures which included the membrane, and others which only passed near it, and killing the animals at various periods after the operations (made as accurately comparative as possible). The result was that nearly all the animals recovered; but in those where the more superficial sutures were used there was a portion of the parietes left destitute of peritoneum, and this defect was supplied by adhesion of intestine or of omentum. In two cases where omentum became adherent, the motions of the dogs were materially interfered with. In those cases where the peritoneal edges of the wound had been included, the union was so perfect that it was difficult to detect the line of union two or three weeks after the operation. This was explained by the observation of a case in which a woman died within two days after ovariotomy. The hare-lip pins which had passed through the peritoneal edges were quite concealed from view and protected from contact with intestine, partly by folding of the peritoneal edges together, and partly by effused lymph. Mr Wells said he had preserved many of the most striking specimens, and would be happy to show them to any gentleman who was interested in the subject.

Dr TYLER SMITH had recently attended a case which strongly exemplified the good effects of bringing the edges of the peritoneum together by the sutures. After union of the external wound and the removal of the sutures, suppuration took place along the whole line of incision, extending through the entire thickness of the abdominal wall. The peritoneum had, however, healed so perfectly that no pus found its way into the peritoneal cavity. In this case, silk sutures had been employed. The patient recovered, but this would have been hardly possible unless the edges of the peritoneum had been brought together, so as to produce union by the first intention. It was unnecessary to pierce the edges of the peritoneum to effect this. It was sufficient to take up the tissue immediately above the peritoneum at the edge of the incision, without passing the needle through the peritoneum itself.

Dr GRAILY HEWITT was induced to believe, from the experience afforded by the cases of ovariotomy he had witnessed, that the inclusion of the edges of the peritoneum in the sutures was a part of the operation to which great importance was to be attached.

Mr SPENCER WELLS said that when metallic sutures were used, and the deep ones were removed on the third day, he had never seen any suppuration in their track.

Dr TANNER said he had been led by an observation of Mr Adams, at a meeting of the Medical and Chirurgical Society, to avoid the peritoneum, but for the future he would follow the plan advocated by Mr Wells.

Mr SPENCER WELLS communicated a

CASE OF DELIVERY OF A LIVING CHILD THIRTEEN MONTHS AFTER OVARIOTOMY.

The child was delivered when the pregnancy had advanced to the eighth month. The mother and child have gone on well. The age of the mother was forty-three years. The fact that well-authenticated cases of childbirth after ovariotomy are rare, had induced the Author to lay the case before the Society.

Dr HERBERT BARKER read a paper on

ANNULAR LACERATION OF THE CERVIX UTERI.

The term "annular" was chosen to distinguish that form of laceration during labour by which a complete ring of uterine structure, consisting of the cervix and os uteri, is separated from the remainder of that organ, the child having passed through the laceration, and not through the os uteri. The cause of this kind of laceration is, the protracted pressure of the head against a circle of the uterine parietes in a contracted pelvis,—perhaps, also, conjointly with a sharp linea ileo-pectinea. In the case related, the Author was called, on the fourth morning of labour, to a primiparous patient, forty-two years old, when he found the os uteri was not dilated larger than a florin, the pelvis contracted, and the bladder much distended. Soon afterwards, an ear could be felt under the pubes, through a transverse laceration in the cervix uteri, anteriorly. An attempt was made to deliver with the forceps, but unsuccessfully, and craniotomy was performed. After the birth of the child, a circular mass was found in the vagina, consisting of the os and cervix uteri, separated from the body of the uterus at every point, with the exception of an inch and a half posteriorly. The os uteri was of the size of a florin, and its margin thin, even, complete, and well defined. The lacerated edge was jagged, rough, rather thicker than the margin of the os, but not so thick as the intervening uterine texture. The colour of the entire mass was of a purplish-red, venous tinge. There was no hæmorrhage. It sloughed away on the third day. The catheter was required for seven days afterwards. The patient recovered, and the catamenia returned. With regard to the treatment, Dr Uvedale West, in a letter to the Author, writes that in such a case he would endeavour to dilate the os uteri, by introducing first one, then a second, then a third and a fourth finger, side by side, to procure sufficient dilatation to admit either the vectis or the forceps.

SPECIMEN OF THE EFFECTS OF RECKLESS VACCINATION.

Dr DRUITT exhibited two coloured drawings showing the happily rare effects of vaccination, performed, he believed, in a recklessly severe manner. A surface, one inch by three-quarters, had been scratched all over by ivory points, and the whole surface had sloughed, leaving an enormous cicatrix. It was a question whether the effects of vaccination suffer any diminution by the entire destruction and separation of the injured part.

Mr JAY thought that there could be little doubt that such an occurrence as that described by Dr Druitt would greatly interfere with the protective efficacy of the vaccination. The early authorities considered that the occurrence of erysipelas interfered with its due influence, and early sloughing of the part operated on, especially where it took place before the appearance of vesicles, must cause the vaccination to be considered wholly useless. He regarded the local and constitutional effects of vaccine inoculation as distinct, and that the former was in a great degree the measure of the latter effect. As the result of observation, he was disposed to think that, for the perfection of this constitutional influence, some days (probably from eight to ten) were required. This active conversion of the whole system into the requisite condition did not appear to him to take place completely in every case, for a certain number of children vaccinated would, on the eighth day, present a few, perhaps one or two, nearly invariably small and retarded vesicles; whilst other children, vaccinated at the same time and in the same manner, would have vessels perfectly normal, and as numerous as the punctures which had been made. In the latter cases it was not very uncommon, especially in warm weather, for an eruption of papulæ to occur over the surface, which eruption was rarely or never seen in the cases in which few vesicles resulted. Reserving a fuller statement perhaps for some other opportunity, he might say, that some time ago he had grouped together a number of cases, at various ages, in which vaccination produced fewer than three vesicles, as the result of seven or eight punctures. He found that in children under three months these partial failures (if he might so call them, for they appeared related to unsuccessful cases) occurred, out of 142 cases, in the proportion of 26·7 per cent. At three months, in 211 cases, they occurred in the proportion of 18 per cent. Above three months, and under one year, in 94 children, the proportion was 8·5 per cent.; and in 54 children above one year, not one single case occurred in which all the points of insertion did not take effect. These results have led him to question whether, in much of our vaccination, there was not a deficiency of protective power, not so much from want of care or dexterity (of which, however, as causes of imperfect vaccination, he had no doubt), but on account of a not uncommon deficiency of a due susceptibility to vaccine inoculation observable in weakly and ill-nourished children of delicate mothers, and in others, which we may, perhaps, be enabled better to distinguish at a future time. In these cases, it would be well to defer vaccination for a few months, and then to use redoubled necessary to avoid the probably imperfectly-matured and weak lymph in these retarded cases as sources of supply, notwithstanding that the absence of areola invited its employment. He trusted this brief statement, after some years' experience, might not be considered irrelevant.

ON A SYMMETRICAL DISTORTION OF THE PELVIS, THE RESULT OF UNEQUAL LENGTH OF THE LEGS.

Dr ROBERT BARNES described a case of oblique distortion of the pelvis in a woman whose first labour had been terminated by craniotomy, the second by the forceps. In the second labour chloroform had been given; mania followed. A minute examination after recovery showed that the left leg was an inch shorter than the right; it had been so from childhood, owing to a fracture of the left ankle. The right half of the pelvis had undergone more active development than the left; it was larger in all dimensions. The symphysis pubis was not in the median line, but much to the left. The Author explained that this was a form of distortion a type of others, of the same kind though perhaps less in degree, resulting from minor degrees of claudication, or of unequal force of the muscles of the two legs. In such a case he was of opinion that the best mode of delivery was to turn the child, so as to bring the occipital, or larger end of the head, into relation with the right or more capacious half of the pelvis, instead of attempting to drag it through by forceps with the occipital directed to the contracted side of the pelvis, or of destroying the child.

Mr ROBERT HARDEY, of Hull, related a

CASE OF ABNORMAL GESTATION.

In this case the unusual character of the tumour and of the symptoms induced the Author at first to

suppose the case to be one of extra-uterine, perhaps tubal, gestation. Labour supervened, and no change appeared to take place in the lower segment of the uterus. It appeared as if a stricture of some kind separated the body of the uterus, which lay to the left side, from the lower part, which was unlike that of an impregnated uterus. Delivery took place, in the Author's absence, of a seven months' child. Afterwards it appeared that this was the third labour; that an injury had been sustained at the end of the third month of her first pregnancy, abortion following next morning; that her second pregnancy terminated by abortion also at the end of the third month; and the Author believes that in consequence of the injury a band had formed, constricting the uterus, and causing the difficulty of the case.

The PRESIDENT communicated the following

CASE OF SPONTANEOUS SEPARATION OF THE PLACENTA IN A CASE OF SEA-SICKNESS.

The placenta was completely separated, and lay in the vagina. There had been considerable hæmorrhage. The patient had been constantly sick during a voyage from St. John's, Newfoundland, to Prince Edward's Island (of six to ten days' duration). Arrived in port, an examination was made, and the delivery (at term) completed. The mother did well.

The PRESIDENT communicated to the Society a

CASE OF CRANIAL BLOOD-SWELLING, ITS CONTENTS AND APPEARANCE AT THE TIME OF BIRTH.

This case was that of an infant found in a canal. At the inquest held on the body, a verdict of "still born" was returned. The child had never breathed. The labour had been, Mr Jeffery believed, protracted.

Dr G. D. GIBB related a case of

PELVIC CELLULITIS AFTER A FIRST PREGNANCY, FOLLOWED BY SUPPURATION OF THE BACK AND FRONT PARTS OF THE VAGINA; RECOVERY.

In this case, nearly eleven weeks after the first symptoms declared themselves, the abscess pointed at the lower and back part of the vagina, and spontaneously evacuated itself. By careful management and a liberal diet, the issue of the case was successful.

Dr J. G. SWAYNE then related a

CASE OF DOUBLE MONSTROSITY.

This was an interesting case of double monstrosity: union between the two fœtuses existed from the umbilicus to the top of the thorax; the left fœtus much larger than the right. Two of the arms were united as far as the wrist. A minute description of the dissection of the monstrosity then followed. Three large drawings illustrated the description.

Dr TYLER SMITH communicated to the Society

FOUR CASES OF PUERPERAL PERITONITIS, IN WHICH ALBUMINURIA WAS PRESENT.

In these cases, which occurred in the Maternity of St. Mary's Hospital, attacks of peritonitis occurred after labour in patients suffering from albuminuria, and the fever and inflammatory affections appeared to be caused by the renal disorder.

MEDICAL SOCIETY OF LONDON, DEC. 17TH.

A. B. GARROD, M.D., F.R.S., PRESIDENT, IN THE CHAIR.

Dr COCKLE read a very interesting, instructive, and highly-suggestive paper

ON INSUFFICIENCY OF THE AORTIC VALVES IN CONNECTION WITH SUDDEN DEATH.

The Author commenced the paper by the consideration of some points of the physiology of the circulation of the blood in the coronary arteries. After reviewing the various arguments respecting the time and manner in which the injection of these vessels with blood took place, he expressed himself as inclining to the opinion that the supposition of their receiving their supply during the systole of the aorta best harmonised with the pathology of cardiac syncope, under the conditions named.

He particularly referred to the experiments of Bernouilli on the passage of fluids through secondary tubes having a certain relation to the main trunk. He next adverted to the important function of the aortic sigmoid valves, in supporting the column of systemic blood, and affording to the ventricle a momentary respite from active labour. But when these floodgates, barred by the backward blood, refused to open, or became too narrow ever again to close, then the heart, baffled by the unusual though intermitting effort, or exhausted by its necessary constancy, gradually sustained such injury in its vital and physical endowments as to be no longer compatible with health, or even with life. He wished it, however, to be understood that his remarks were limited to the state of insufficient closure, and that he desired to show how, from such imperfection, the conditions were afforded for sudden death. He thought a practical division might at times be made of the disease into the three stages—the Incipient or Irritative, the Physiological or Confirmed, and the Degenerative.

The first stage, when the result of rheumatic valvular aortitis, was one simply characterised by the signs of general cardiac excitement, and in no wise susceptible of physical differential diagnosis from mitral disease. The second stage was characterised by the physiological hypertrophy of the left ventricle, and throbbing of the visible arteries. Here there was an actual addition of healthy contractile tissue, affording a genuine compensation under injury sustained. The importance of this accommodation of nature would be at once manifest, if it were but considered how impossible it would be for the circulation to continue if the strength of the left ventricle were enlarged, and any great amount of reflex occurred. For the requirements of the system, there must be as much blood sent into the aorta *plus* the quantity which reflows. To make this provision is the final cause of the hypertrophy of the left chamber. The amount of collapse of the arteries, practically speaking, might be taken as the measure of the extent of patency of the aortic valves.

This second stage might, at times, last for years without passing its limits. But, generally, after a period more or less long, further changes occurred. The greatly-enlarged left ventricle might, by pressing upon and condensing in part the left lung, implicate the right heart.

The strict correlation existing between hypertrophy of a ventricle and atheromatous degeneration of its discharging tube was particularly insisted on. Such change induced loss of elasticity of the aorta, and was productive of the worst results with regard to the nutrition of the cardiac walls. Eventually, the left ventricle, from its constant overwork and under-nutrition, undergoes an irreparable change of a fibroid, or more commonly fatty nature. The extreme limit of the third or degenerative stage is then attained.

The degenerate ventricle has also acquired a *maximum* of dilatation. On the sudden occurrence of shock either moral or physical, or from mere exhaustion, should prolongation of the diastole of the heart occur, and the *hiatus* at the aortic mouth be sufficiently large, the systemic blood flows unimpeded into the left chamber, which acts as a vast reservoir. The general system and brain are thus robbed of their needful stimulus. The coronary arteries, on the theory given, remain unfilled. Add to this the tendency to paralysis of the left ventricle from the enormous blood-pressure on its walls, and the sum of the conditions is given under which sudden death occurs by what is known as cardiac syncope.

The Author next alluded to some points connected with the physical signs, and pointed out the curious clinical fact, that occasionally, in well-marked aortic insufficiency, the first sound of the heart became extinct, although the mitral valve was healthy. He had often tried to account for this circumstance, but could arrive at no very satisfactory conclusion, until he became acquainted with the views of Traube, of Berlin. These were explained at length; but Dr Cockle pointed out that, from the anatomical connection between the aorta and one curtain of the mitral valve, a pathological cause for modification of the first sound would occur, should the atheroma extend from the diseased aorta to the point of the mitral valve in question. He criticised the ordinary teaching, that the differential diagnosis of aortic insufficiency could be made, even in part, by the normal sound of the pulmonary sigmoid valves auscultated to the left side of the sternum. If aortic murmur were at all intense, or, *à fortiori*, musical, it invariably obscured the sound of the pulmonic valves. A marked diastolic murmur at the left apex might, practically speaking, be regarded as the expression of aortic insufficiency. Mere murmur, however, only indicated the kind, but not the degree, of the lesion. This must be estimated by the observed amount of collapse of the visible arteries.

The paper was concluded by some rules of treatment, especially with regard to the first or irritative stage of the disease. This, certainly, was amenable to treatment. In the second stage, unless any of the accidents of the affection supervened, remedial measures were absolutely contra-indicated. In the degenerative stage, the use of any of the ordinary agents—iron, strychnine, &c.—was very questionable. They could not rechange fatty or fibroid tissues into healthy muscle. Should cardiac syncope be imminent, the recumbent position, external and internal excitants, and, beyond all, the sudden application of cold to the region of the heart, should be resorted to.

The PRESIDENT (Dr GARROD) made a few pertinent and complimentary remarks on soliciting a discussion, by the Fellows, of the interesting pathological points which had been enunciated in the paper read by Dr Cockle. A discussion ensued, which, although rather desultory, tending to range into too extended a field of inquiry, nevertheless pretty well exhausted the subject so far as our present pathology permits. In this discussion Drs Halford, Bird, Webb, Richardson, Hyde Salter, and Camps joined. It assumed three modes of viewing the heart's action in relation to disease—namely, its physical action, its vital action, and its pathological action.

Dr HALFORD commenced the discussion by some remarks upon the physical action of the heart's function, and the relative conditions of the mitral and aortic valves in producing the first and second sounds. He also referred to the conditions and influence which produced tension of the mitral valves. Thus, we understood him to say that if the semilunar valves were closed, there would not be tension of the mitral valves. It was necessary that both valves should be open. He did not think that the physical condition of arteries passing off at right angles had any influence upon the circulating fluid. The same physical arrangement occurs in other parts of the body.

Dr BIRD considered Dr Cockle's paper had very cleverly elucidated the diseased conditions of the heart's action, and was an important testimony. He himself did not think that either the *systole* or *diastole* of the heart had much to do with the first or second sounds. He took the vital view of the question, and considered that these sounds depended upon the condition of and proceeded from the muscles. He related the history of two cases, both of which were characterised by want of muscular power. The first patient, a lady whom he visited at Tunbridge Wells, attacked with rheumatism, recovered from a most exhausted condition with very little medical treatment: mustard poultices were applied on both the back and chest. This lady had some years previously been under the treatment of Dr Burns and Dr Abercrombie of Edinburgh for a similar attack. The second case was an Undergraduate of Oxford, who came to his home from the University in a bad state. He had rheumatism, and the aortic valves were implicated. He had his entire body enveloped in cotton wool, and was soon cured of the rheumatism. Being so much better, he very ignorantly and suddenly removed the cotton wool from his body. The consequence was, a state of extreme debility ensued, to an extent threatening life. This induced almost complete suppression of pulse and congestion of lungs; and the function of the bosom-lung became nearly suppressed, and permanent hypertrophy of the lung threatened to be the result. The treatment adopted in this case was hot baths strongly impregnated with alkalies.

Dr RICHARDSON considered Dr Cockle's paper very valuable, and coincided with his pathology. Within the last five years he had seen many hundred cases of heart disease, but had met with but one case like Dr Bird's. He took the pathological view of the subject. Dr Richardson differed from Dr Bird in considering these cases not characterised by loss, but rather by an increase of muscular action. There existed more tension of the valves, both aortic and auricular (as we understood him to say), than relaxation. He had seen great temporary relief afforded by taking away locally a small quantity of blood to-day, and repeating the same on the morrow. Dr Richardson went fully into the subject, but our space will not permit us to follow him.

Dr HYDE SALTER made a few remarks upon the difference of the arterial and capillary circulations in the heart and elsewhere, which he elucidated by some curious facts. He said, the coronary arteries may be filled at one moment, and the capillaries at another. His experience quite confirmed Dr Cockle's statement, attributing aortic loss of function to *atheroma* and fibrous degeneration. The treatment he recommended, and had seen great benefit from, was the use of *elaterium*. By administration of elaterium, you bring away the watery particles of the blood, and thus prevent the necessity of abstracting blood from the system.

Dr WEBB and Dr CAMPS also made a few remarks. The latter gentleman thought reference to the first principle of logic very necessary in this discussion, and that a correct definition of terms should be given. He asked, was *dilatation* and *relaxation*, in reference to the heart's function, the same thing? and if *diastole* and dilatation were also considered to be similar, and if *systole* and contraction were synonymous? An answer to these questions was indis-

ponsable in this discussion before entertaining Dr Halford's physical views. Relaxation of the muscular fibres of the heart had nothing to do with it.

Dr Cockle replied generally. He referred to Dr Richardson's numerous experiments upon animals, of which he had availed himself, and from which he had derived much information. They were particularly valuable in explaining aortic regargitation. As he had not gone into the general treatment, he had made no allusion to treatment by elaterium, as recommended by Dr Hyde Salter. He depended principally in his treatment, which was limited to the first stage, upon the administration of stimulants and excitants.

Births, Marriages, and Deaths.

BIRTHS.

Hubbard.—December 13, at Norland terrace, Notting hill, the wife of Henry W. Hubbard, Esq., M.R.C.S., of a daughter.

Rayner.—December 13, at Great Malvern, the wife of W. T. Rayner, M.D., of a son.

Simpson.—December 13, at Canonbury street, Canonbury, the wife of Archibald Simpson, M.D., of a daughter.

MARRIAGES.

Curtis—Braund.—December 15, at St Paul's, Camden square, Albert Curtis, Esq., M.R.C.S., of Staines, Middlesex, to Maria, younger daughter of William Braund, Esq., of St Paul's road, Camden square.

Webb—Duncan.—December 18, at Holy Trinity Church, Colchester, Vere Webb, Esq., Staff-Surgeon, to Fanny Elizabeth, youngest daughter of the late Peter Duncan, Esq., of Regent's park.

DEATHS.

Atwell.—December 9, James Buckley Falconer Atwell, of Lympstone, near Exeter, M.R.C.S. Eng., L.S.A. Lond.

Burn.—December 1, at Sussex terrace, Old Brompton, the wife of Alexander Burn, M.D., Surgeon-Major, Bombay Army.

Colvan.—December 13, John Colvan, of Newry, Co. Down, Lic. and L. Med. K.Q.C.P. Irel., L.M. Univ. Trin. Col. Dub., M.R.C.S. Eng., F.R.C.S. Irel., aged 70.

Fearon.—December 10, George Fearon, of Edgbaston, Birmingham, L.R.C.S. Edin.

Gillespie.—October 3, at Richmond, Victoria, Australia, D. M. Gillespie.

Jolit.—December 15, suddenly, at the French Protestant Church, St Martin's-le-Grand, Isaac Jolit, aged 67.

Kilby.—November 17, at Newbiggin-by-the-Sea, aged 45, Frederick Kilby, Esq., Surgeon, youngest son of the late John Kilby, Esq., of York, much and deservedly respected.

Parrott.—November 10, John Parrott, of Clapham common, Fell. and M.R.C.S. Eng., formerly Master of the Society of Apothecaries, aged 70.

Parry.—December 5, at Mold, Flintshire, Thos. Parry, formerly Surgeon to the Royal Merionethshire Militia, aged 69.

Skidmore.—December 7, at Leicester, suddenly, Peter Skidmore, of Ashover.

Wallace.—December 11, at Charlotte street, Perth, the wife of Isaac Wallace, M.D.

Woolley.—May 30, at Kensington, New South Wales, George Woolley, M.D.

MEDICAL NEWS.

Royal College of Surgeons.—The following Members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery, at a meeting of the Board on the 19th inst.:—John Christopher Armstrong, Gravesend—diploma of Membership dated May 16, 1859; William Batho, Amesbury—Nov. 13, 1860; James Bird Bickerdike, York—Feb. 23, 1859; William Callender, Hunshaugh—Dec. 19, 1856; Alfred Frederick Strafford Clarke, Gordon square—Nov. 15, 1860; Brauthwayte Beevor Ford, Longton—Nov. 15, 1860; William Henry France, Sheffield—Aug. 2, 1860; William Paine, Exeter—April 18, 1860; John Roberts, Crûg, Carnarvon—April 4, 1859; Thomas Whitehead, London—Oct. 6, 1848; Edward Parker Young, Delamere crescent—Nov. 15, 1860; Henry James Young, Bath.—Jan. 21, 1859.

Apothecaries' Hall.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, Dec. 13th, 1860:—John Boyd Caskie, Largs, Ayrshire, N.B.; Albert Curtis, Staines, Middlesex; Henry May, Birmingham; Ebenezer Nicholas, Market Deeping; Thomas James Schollick, Ulverston, Lancashire; Brinsley Marcius Walton, Hurstpierpoint, Sussex; Robert Wrixon, Devonshire terrace, Camden town. The following gentlemen also on the same day passed their first examination:—George Howarth, Southport, Lancashire; John E. Kilburn, West Auckland, Durham; Edward Allan Maling, Sunderland; Edward Humphery Williams, Carnarvon, N.W.

Appointments.—Mr H. M. Leppington has been elected Mayor of Grimsby, Lincolnshire. Dr C. Murchison has been appointed Assistant-Physician to the Middlesex Hospital; Dr W. O. Priestly, Physician-Accoucheur to the Middlesex Hospital.

The Stomach of London.—The appetite of London consumes every year 371,000 oxen, 30,000 calves, 1,500,000 sheep, and 30,000 swine.

The Turkish Bath Movement.—A prospectus has been issued of the London and Provincial Turkish Bath Company, with a capital of £100,000 in shares of £5 each.

The Anti-Tobacco Movement.—At a meeting of the British Anti-Tobacco Society lately held in Edinburgh, Professor Miller moved the following resolution:—"That as the constituent principles which tobacco contains are highly poisonous, the practices of smoking and snuffing tend in a variety of ways to injure the physical and mental constitution."

Thomas Smethurst.—In the Probate Court last week, Thomas Smethurst, who was convicted of the murder of Miss Isabella Banks, and afterwards pardoned, applied for probate of her will, which was dated May 3rd, 1859. The application is opposed by the next of kin of the deceased. Some formal proceedings took place, but the day on which the cause will be gone into is not yet known.

Extraordinary Endurance of Pain.—Mr Hutton, of Radley, was caught in some mill machinery, and his arm terribly crushed. He extricated himself, and stopped the machinery. Allowing no one to convey the intelligence to his wife, he concealed the injured arm, and walked home. He proceeded into the house with all his usual calmness, took down a book from the shelf, and commenced reading it for a few minutes, then gradually broke the news to his wife. Surgical assistance was procured, and throughout the necessary manipulations the patient endured bravely his sufferings, aided by his wife, whom he had inspired with fortitude and resignation. Unfortunately, amputation was necessary.

A Fact for Physiologists.—At the Middlesex Sessions, on the 17th inst., Henry Hamilton, eighteen years of age, was tried with two other prisoners for an ordinary theft. Boden, 11 D, and Deeble, 147 D, said they knew the prisoners, and mentioned the extraordinary circumstance that Hamilton was one of a family of thirty-two children. His father was sixty-six years of age, and had had two wives, by one of whom he had had thirty children, by the other two, and of them all twenty-four were now living. He was married to his first wife forty-eight years, and the youngest of his thirty-two children was now seven years old.

Unwholesome Meat.—At the last City Sewers Commission, in respect of the markets and slaughter-houses, Dr Letheby reported that 41331b., or nearly two tons, of meat had been seized during the week as unfit for human food. Of this 3080 lb. had been seized in Newgate Market, 4581bs. in Leadenhall, and 5951b. in Aldgate and Newgate. 25331b. were seized on account of it being diseased, 597 because of its putridity, and 1003 by reason of the animals having died from natural causes. All of it had been sent to the boats, and destroyed as unfit for human food.

SULPHURIC ACID AS A REMEDY FOR TÆNIA.

Dr [illegible]ch states that several cases have occurred to him which sulphuric acid has proved completely effic[illegible]s in the destruction of tape-worm. He ord[illegible]-Acid. sulph. aromat. one oz. to one pint and a [illegible] water, directing the patient to drink of it a[illegible]n as he can until it has been all taken—'American Journal of Medical Science.'

APPOINTMENTS FOR THE WEEK.

Wednesday, December 26.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, December 27.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Surgical Home.—2 p.m.

Friday, December 28.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, December 29.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, December 31.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.

Tuesday, January 1.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Blood in Mania. By W. Charles Hood, M.D.

NOTICES TO CORRESPONDENTS.

Mr James.—Forwarded.

Dr Graily Hewitt.—Received.

Mr S. L. Gill.—We should be obliged by further information.

Mr Croxton.—Received.

Chirurgus (Subscriber).—We have no doubt that epilepsy may be induced by the cause adverted to. Various cases are on record in illustration of it; and on the other hand, cases of general paralysis, which are frequently preceded by epilapsy, are also characterised in the early stages by extreme sexual excitability.

Dr Howard.—Yes.

A Student.—1st. No.—2nd. Yes.

Omega.—The changes are so rapid and numerous, that we advise you to apply for information to the Secretary of the Board.

A Poor-law Medical Officer.—The Poor-law Board has no intention, we believe, to introduce a Bill next Session.

A. L.—The determination of the nutritive value of a mixed dietary is a matter of somewhat difficult calculation. That which you have provided is unusually complex. We have no time to analyse it: as a rule, however, you should extract all the carbon as the representative of the respiratory elements, and all the nitrogen as the representative of the nutrient elements. Paupers require about 4 oz., or less, of the latter daily, and 8 oz. of the former. It requires 10 oz. of carbonaceous and 5 oz. of nitrogenous matters to keep a soldier or sailor in fighting condition. These figures will be a sufficient basis for you.

A Country Subscriber.—1st. We are unable to supply the information.—2nd. It cannot be done.

Mr Baker is thanked.

W. P.—1st. We do not think it would be possible.—2nd. It is immaterial.

A Member of the College.—The intended testimonial to Mr Belfour is to be a donation by the Council. There is a letter in the present Number of the Circular upon the subject.

M.D.—We are obliged to you for your compliments. If each subscriber would imitate your example, and introduce a new one, it would be the best possible mode of serving us, and of giving effect to good wishes.

M. R. D. (Yorkshire) writes to us to say that in a small hospital, of which he has charge, "the average age of the women (ten inmates) is eighty-one years and three months, all able to go about; the men (ten also), is seventy-two years and two months. There are children in the hospital also, but that is of no consequence. Their condition is somewhat above that of the pauper."

[We are unable to give the detailed information respecting the Paris Hospitals required by our correspondent.]

Stanley.—1st. We cannot tell; apply to the Registrar.—2nd. You should consult the back numbers of the Medical Circular.—3rd. We do not consider the work of any value.—4th. There is such a Society—the Medical Registration Society, but it has no funds; we are unacquainted with the name of the Secretary.

Mr Jeffery's letter referring to the Public Banquet to Dr Copland has been received. He shall have a private letter.

Dr Bell's letter on a New Operation for Amputation of the Foot shall appear next week.

Mr Horace Swete shall receive a private note.

Dr Tucker.—Note received. We are glad to hear of Dr Barter's determination.

Harpen.—Next week.

A Subscriber on "Snoring," next week.

Classical and Mathematical.

—Dr STEGGALL (assisted by the Rev. L. J. Lovekin and T. Hogan, Esq., M.A.) Prepares Gentlemen for their Examinations at the following Boards:—Matriculation Examination of the London University; Preliminary Examination at Apothecaries' Hall; Fellowship Examination at the Royal College of Surgeons; Preliminary Examination at the Royal College of Surgeons.—For terms, &c., apply to Dr STEGGALL, before 1 and after 3 o'clock daily, at 2 Southampton street, Bloomsbury square.

N.B.—No Vacation during the Summer months.

CHLORODYNE.

J. T. Davenport begs to direct attention to the disgraceful and fraudulent practice of certain parties who apply the term "CHLORODYNE" to compounds of THEIR OWN MANUFACTURE, WELL KNOWING that the word is SPECIFICALLY applied to a remedy SOLELY DISCOVERED and INTRODUCED by Dr J. COLLIS BROWNE, M.R.C.S.L. (late Army Medical Staff), the formula of which is confided to J. T. DAVENPORT, and NONE other;—hence the assumption of the title, claim to discovery, or manufacture of CHLORODYNE by any other persons is a direct palpable deceit and imposition.

The Medical Testimony published on the extraordinary properties of this remedy is exclusively applied to

Dr J. COLLIS BROWNE'S CHLORODYNE.

WHOLESALE DEPOT,

33 Great Russell street, Bloomsbury square, London.

Millikin, late Bigg and Millikin,

Surgical Instrument Maker and Anatomical Machinist to Guy's and St Thomas's Hospital, No. 9 St Thomas's street Southwark S.E.

Loan, Discount, and Deposit BANK.

Established 1849.—145 Blackfriars road. S.

DEPOSITS.—Sums of £1 and upwards received, bearing interest at from 5 to 10 per cent., withdrawable as per agreement.

DISCOUNT.—Approved Trade Bills negotiated at two days' notice.

LOANS.—From £6 to £200, repayable by easy instalments, on approved Personal Security, Bills of Sale, Mortgages, Life Policies or otherwise.

Prospectuses, and every Information, may be obtained by letter or personal application.

EDWARD LEWIS, Manager.

145 BLACKFRIARS ROAD, S.

Liquor Castanea Equina.—

Messrs. REW and Co. respectfully solicit the attention of the Profession to this Preparation of the Horse-Cheanut; taken internally for Rheumatic Gout and Rheumatism, it is a safe, agreeable, and most efficacious remedy.

Dose, two to four drachms. Price 12s. per pound.

The Oil of Horse-Cheanuts applied externally for enlarged and stiff joints, acute or inflammatory pain of any kind, gives almost immediate relief.

These genuine Preparations of the Horse-Cheanut are prepared only by REW and CO.

LITHIA WATER, LITHIA POTASH, and LITHIA AMMONIA WATER. These Waters are prepared according to the Instructions of Dr Garrod, and each bottle is guaranteed to contain the proper proportion of Lithia. 5s. per doz.

R. M. REW and CO., Operative Chemists, 282 Regent street, London.

TO SURGEONS, DENTISTS, &c.

The Best House in London

for SECOND-HAND INSTRUMENTS is Mr WM. LAWLEY'S, Lombard House, 78 Farringdon street, City.

Established upwards of a century.

A first-class full SURGEON'S ARMY CASE for Sale.

N.B. The largest stock of Second-hand Dissecting Cases London. Also, A great variety of New and Second-Army and Navy Regulation Cases.

Instruments Bought, Sold, or Exchanged.

Chlorodyne.—R. Freeman,

Pharmaceutist, Kennington road, London, S., informs the Profession and Trade that he has FOR YEARS MADE, and extensively used in his business, Chlorodyne; and that he is supplying it in one-ounce stoppered bottles at 1s. 6d. each, and in four-ounce bottles 5s. each. He guarantees it to be uniformly and properly prepared, and superior to any other makers', though their charge be ever so exorbitant; and he trusts that the lowness of price at which he offers it will allow the Profession to use it in common practice and at public institutions, so that its extraordinary beneficial effects may be enjoyed by the poorest sufferer. Sold by all Wholesale Druggists.

TO THE PROFESSION.

Messrs M'Gowan & Danks

(THE PRINTERS OF THIS JOURNAL)

Are prepared to forward Estimates, to those requiring the same, for any description of Work connected with the Printing Business.

Messrs M'G. and D. are enabled, from the facilities which they possess, to execute whatever may be entrusted to them with economy and despatch.

Letters addressed to No. 16 GREAT WINDMILL STREET, HAYMARKET, will meet with immediate attention.

*** There is at the present time an opening for the Printing (and Publishing if wished, of a Weekly Periodical.

Huxley's Spiral Abdominal

BELT is constructed on a principle which secures the required support, without being liable to displacement, and is invaluable, when properly constructed, in cases of Pregnancy, Obesity, Ovarian Dropsy, &c. When required, it is fitted with Air-pads for Umbilical, Inguioal, and Femoral Hernia, and Band with Air-pad for Prolapsus Uteri and Prolapsus Ani. These goods, in addition to Stockings Thigh-pieces, Knee-caps, &c., supplied 30 per cent. lower than the prices hitherto charged every article being of the very best quality.—Measures required: Circumference at a, b, c; depth, from a to c.—Priced and Illustrated Catalogues on application to

E. HUXLEY,

12 Old Cavendish street, Oxford street, W.

PULVIS JACOBI *VER.*, NEWBERY'S.

To the Medical Profession of Great Britain and Ireland.

GENTLEMEN,—We beg to call your attention to the following extract from a Paper by the late John Cheyne, M.D., F.R.S.E., M.R.I.A., Physician to the Hardwicke Fever Hospital, Dublin, and Physician-General to His late Majesty's Forces in Ireland, &c., &c., contained in "*the Dublin Hospital Reports*," *vol.* I, *p.* 320.

"The following very simple method of "exhibiting JAMES'S POWDER, in cases "of undue determination of blood to the head, "is that which I have generally pursued. The "patient is made to begin with a very moderate "dose, not more than two grains at bedtime, "and to increase the dose by half-a-grain every "night, until some sensible effect is produced "upon the stomach, bowels, or skin. Should "the stomach be affected with sickness, the dose "must be lessened, by one grain on the following "night. *By the addition of a little rhubarb "to it, a larger quantity of* JAMES'S "POWDER *may be administered than the "stomach could otherwise bear.* If the skin "is softened, or the bowels affected, the dose "should not further be increased, but it must be "repeated every night for a considerable length "of time: in several instances I have known "eighteen or twenty grains taken for a consi-"derable period without any inconvenience."

To secure the dispensing of the *original* preparation, which, for 114 years, has been sold by the house of Newbery and Sons, in St. Paul's Churchyard, it is necessary to prescribe it as "PULVIS JACOBI VER., NEWBERY'S," otherwise another article (wanting in the best properties, and recommended to be given in a different code of dose, *though called by the same name*) may be substituted for the original medicine.

This substitution must bring disappointment, and of course lead Practitioners to give up prescribing Dr. James's Powder altogether, or to regard it as a preparation on which no dependance can be placed.

FRANCIS NEWBERY AND SONS.

45, St. Paul's Churchyard, London.

Prices for Dispensing ½ oz. Bottle 3*s.* 4*d.*, 1 oz. 9*s.* Usual Discount to the Profession.

NOTICE Letts's MEDICAL DIARY,

arranged for vaccinations, Accouchements, Nurses' Addresses, &c., Patients' Names with column for Daily Visits. Neatly bound in cloth, pocket book, flap, pencil, and clasp, 2s.; French Morocco Tuck, two pockets and pencil, gilt edges, 3s.; best Pocket Morocco or Russia Book, 10s. 6d.; with divisions for instruments, 17s. and 15s. (Double the substance, 1s. 6d. extra.) Instrument Cases for ditto, 4s. 6d.

The other Editions of LETTS'S DIARIES commonly used by MEDICAL MEN, are Nos. 1, 2, 5, 9, 10, 12, 14; the Professional Appointment Diary; the Monthly Professional Diaries; Medical Visiting Lists, etc.

LETTS'S READING EASEL for INVALIDS, from 20s. to 40s. Sold by all Booksellers.—Fully descriptive catalogues gratis.

LETTS, SON, and Co., STATIONERS, 8 Royal Exchange, London, E.C.

Human Osteology

from France.—RAGINEL, 38 Lndgate hill, City, E.C., London. Patronised by the Royal College of Surgeons of England. Illustrated Osteology on the bones themselves. Very large stock on the lowest possible terms. Disarticulated Skulls, in twenty-two pieces, in box. All the bones of the disarticulated skulls will be fitted in right order in the presence of the purchaser, so as to show that every bone of each set belongs to the same skull; it will be the same for all other disarticulated pieces. Skulls with Sections. Hands and Feet on cat gut. Disarticulated Skeletons, quite complete, with the Skull same body. Articulated Male Skeletons, the bones very well marked.

STUDENT'S CASE OF OSTEOLOGY, COMPLETE.

Splendid Pieces for Lecturers and Museums.

Elastic Supporting Fabrics,

of very superior textures, for Varicose Veins, Accouchement, Spinal Affections, Hernia, &c. Instructions for measurement, and prices, on application to the Manufacturers, POPE and PLANTE, 4 Waterloo place, Pallmall, London, S.W.

RUPTURES. BY ROYAL LETTERS PATENT.

White's Moc-main Lever

TRUSS is allowed by upwards of 200 Medical Gentlemen to be the most effective invention in the curative treatment of HERNIA. The use of a steel spring, so often hurtful in its effects, is here avoided; a soft bandage being worn round the body, while the requisite resisting power is supplied by the MOC-MAIN PAD and PATENT LEVER, fitting with so much ease and closeness that it cannot be detected, and may be worn during sleep. A descriptive circular may be had, and the Truss (which cannot fail to fit) forwarded by post, on the circumference of the body two inches below the hips being sent to the Manufacturer.

JOHN WHITE, 228 Piccadilly, London

Price of a Single Truss, 16s., 21s., 26s. 6d. and 31s. 6d.—Postage, 1s.

Price of a Double Truss, 31s. 6d., 42s. and 52s. 6d.—Postage, 1s. 8d

Price of an Umbilical Truss, 42s., and 52s. 6d. Postage, 1s. 10d.

Elastic Stockings for Varicose Veins,

and all cases of Weakness and Swelling of the Legs, Sprains, &c. They are porous, light in texture, and inexpensive, and are drawn on like an ordinary Stocking. Price 3s 6d. 7s. 6d., 10s., and 15s. each. Postage, 6d.

JOHN WHITE, MANUFACTURER,

228 Piccadilly, London

Lateral and Angular Curvatures of the Spine.

In calling the attention of the Profession and Public to the SUPPORTS made by them, WM. WHITING and SONS beg to state that their extensive experience (over twenty years) warrants them in asserting that the IMPROVED SUPPORT which they now manufacture will be found to be the most effectual of any in use. At the same time, they are LIGHT, COMFORTABLE TO WEAR, AND COMPLETELY INVISIBLE THROUGH THE DRESS, as experienced by the many hundreds of persons of every age and sex who are now using them.

W. W. and Sons would also invite attention to their IMPROVED EXERCISING MACHINES, SPINAL COUCHES, and their various other contrivances required in Orthopædic practice.

Manufactory, 28 High street, Camden town.

N.B.—Makers (by authority) to the Spinal Hospital, Portland road, Regent's park, founded by the late Dr Verral.

Surgical Instruments.—

J. ARNOLD continues to supply Instruments of the best workmanship at moderate prices, manufactured on the premises under his own superintendence.

J. ARNOLD, 35 and 36 West Smithfield, E.C.

Established 1819.

Chiosso's Gymnasium and

SCHOOL of ARMS, 231, EUSTON ROAD, Corner of Gower street North (near University College).

Mr ANTONIO CHIOSSO begs to draw the attention of Parents, Guardians, and all those who have the charge of Youth, to his system of Physical Education, which has proved, through experience, to be the most invaluable means of rectifying Physical Defects in the human organisation, such as Curvature of the Spine, Contraction of the Chest, general Debility of Body, &c., &c. Classes meet every hour of the day, attended personally by Mr Chiosso, from 9 A.M. till 10 P.M.

Fumigations of Sulphur,

Chlorine, Mercury, and simple Hot-Air and Vapour Baths, continue to be administered at No. 40 Great Marlborough street, under the guidance of Dr GREEN, commenced in 1822, and recommended for the majority of long standing complaints.

Nervous and Mental

DISORDERS.—Wyke House, Sion hill, Isleworth, Middlesex, W.—A Private Establishment for the Cure and Residence of Ladies and Gentlemen mentally afflicted.—Proprietor, E. S WILLETT, M.D.
